Free Vibrations of Thin Shells with Isogeometric Approach

Sang Jin LEE
ADOPT Research Group, Department of Architectural Engineering, Gyeongsang National University

Abstract Free vibration analysis of thin shells is carried out by using isogeometric approach. For this purpose, a thin shell element based on Kirchhoff-Love shell theory is developed. Non-uniform rational B-spline surface (NURBS) definition is introduced to represent the geometry of shell and also used to derive all terms required in the isogeometric element formulation. Gauss integration rule is used for stiffness and mass matrices. The present shell element is then applied to examine vibrational behaviours of thin plate and shell structures. From numerical results, it is found be that reliable natural frequencies and associated mode shapes of thin shell structures can be predicted by the present isogeometric shell element.

Keywords: Thin Shell, Isogeometric Analysis, Free Vibration, B-spline, NURBS.

1. INTRODUCTION

There is prominent importance to understand the vibrational behaviours of shells in structural design. So far, many attempts have been made to calculate the accurate natural frequencies and associated mode shapes of shells. The first attempt was made by Love (1888) and Rayleigh (1894) and then Flügge (1934) provided numerical solution of shell vibrations using frequency equation. With the introduction of numerical analysis techniques (Leissa, 1973; Qatu, 1992; Liew, 1995), various types of shells with complex geometry have been gradually tackled. In particular, with the use of FE technologies, thin shells tend to be more widely used in various engineering practices and therefore vibrations of thin shells become more crucial. In recent year, as an alternative method to the FE method, the isogeometric analysis (IGA) concept has been proposed by Hughes et al. (2005). In the isogeometric approach, NURBS (De Boor, 1978) is consistently used to represent both structural geometry and the displacement field. As well-known fact, the NURBS can provide higher continuity of derivatives compared to the interpolation functions such as Lagrange interpolation function. The NURBS basis functions can be also efficiently refined without changing the geometry (Cottrell et al., 2009) and the order of the basis function can be naturally elevated. There have been several applications of isogeometric concept into structural vibrational problem (Hughes and Evans, 2010). In particular, the detailed investigations on the vibrational behaviours of plate and Timoshenko beam are provided by Lee and Kim (2012) and Lee and Park (2013) respectively. As a sequel of the previous study on the vibrations of beams and plates, we here introduce the isogeometric approach to investigate natural frequencies and associated mode shapes of thin shells. For this purpose, a thin shell element based on Kirchhoff-Love shell theory is developed with isogeometric concept. Hence, NURBS definition is introduced to represent the geometry of shell and also used to derive all terms required in the isogeometric element formulation. In addition, Gauss integration rules is used for stiffness and mass matrices. Some benchmark tests are carried out and provided as the future reference solution based on isogeometric approach for thin plate and shell structures.

2. B-SPLINES

2.1 Knot vector

A knot vector $\Xi$ is a set of non-decreasing real values that constitutes a set of coordinates in the parametric space:

$$\Xi = [\xi_1, \xi_2, \xi_3, \ldots, \xi_{n+p+1}]$$

(1)

where $n$ is the number of basis functions and $p$ is the order of the B-spline. A knot vector is said to be uniform if its knots are uniformly spaced and non-uniform otherwise. Moreover, a knot vector is said to be open if its first and last knots are repeated $p + 1$ times. Basis functions formed from open knot vectors are interpolatory at the ends of the parametric interval $[\xi_1, \xi_{n+p+1}]$ but are not, in general, interpolatory at interior knots. It should be noted that we would employ open knot vectors throughout the analysis of laminated plate.

2.2 Basis functions

B-spline basis function (De Boor, 1978) is defined recursively
starting with $p = 0$ as:

$$N_{i,0}(\xi) = \begin{cases} 1 & \text{if } \xi_i \leq \xi < \xi_{i+1} \\ 0 & \text{otherwise} \end{cases}$$

For $p \geq 1$,

$$N_{i,p}(\xi) = \frac{\xi - \xi_i}{\xi_{i+p} - \xi_i} N_{i,p-1}(\xi) + \frac{\xi_{i+p+1} - \xi}{\xi_{i+p+1} - \xi_{i+1}} N_{i+1,p-1}(\xi).$$

### 2.4 B-spline curves

We construct basis functions with the order of a B-spline and an appropriately defined knot vector. The piecewise polynomial B-spline curve $S(\xi)$ of order $p$ can be obtained by taking a linear combination of basis function and control points:

$$S(\xi) = \sum_{i=1}^{n} N_{i,p}(\xi) C_i$$

where $C_i$ is the $i^{th}$ control point. The piecewise linear inter-polation of the control points defines the control net.

### 2.5 NURBS

NURBS can be defined as

$$S(\xi, \eta) = \sum_{i=1}^{n} \sum_{j=1}^{m} R_{i,j}^{p,q}(\xi, \eta) C_{i,j}$$

where $R_{i,j}^{p,q}$ can be written as

$$R_{i,j}^{p,q}(\xi, \eta) = \frac{N_{i,p}(\xi) N_{j,q}(\eta) w_{i,j}}{\sum_{i=1}^{n} \sum_{j=1}^{m} N_{i,p}(\xi) N_{j,q}(\eta) w_{i,j}}$$

and $w_{i,j}$ is the weight associated with the control point.

### 3. KIRCHHOFF-LOVE SHELL THEORY

#### 3.1 Assumptions

The present isogeometric shell element is based on Kirchhoff-Love assumptions:

[A1]. All points lying on the normal of the mid-surface before deformation remain on that normal, which remains the normal of the deformed mid-surface.

[A2]. The distance of a point from the mid-surface remains constant during deformation.

Assumption [A1] is known as the Bernoulli hypothesis in the beam theory and therefore deformations due to transverse shear stresses are negligible. From assumption [A2], strain in normal direction is of no significance so that three-dimensional problem can reduce to a two dimensional surface deformation problem.
3.2 Kinematics

The configurations of shell are described by the mid-surface of shell as illustrated in Figure 1 and the shell mid-surfaces are represented by using natural coordinate system \((\xi^1, \xi^2)\) such as

\[
\mathbf{X}(\xi^1, \xi^2) = \mathbf{X}(\xi^1, \xi^2) + \zeta^3 \mathbf{A}_3(\xi^1, \xi^2) \tag{7}
\]

where \(\mathbf{X}\) is the mid-surface of the shell and \(\mathbf{A}_3\) is the normal to the mid-surface such as

\[
\mathbf{A}_3 = \frac{\mathbf{A}_1 \times \mathbf{A}_2}{|\mathbf{A}_1 \times \mathbf{A}_2|} \tag{9}
\]

in which \(\mathbf{A}_\alpha = \mathbf{X}_\alpha (\alpha \in \{1,2\})\) is tangent vectors on the mid-surface.

The deformed shell can be similarly defined as

\[
\mathbf{x} = \mathbf{x}(\xi^1, \xi^2) + \zeta^3 \mathbf{a}_3 \tag{10}
\]

where \(\mathbf{x}\) is the mid-surface of deformed shell and it can be written as

\[
\mathbf{x}(\xi^1, \xi^2) = \mathbf{X}(\xi^1, \xi^2) + \mathbf{u}(\xi^1, \xi^2) \tag{11}
\]

in which \(\mathbf{u}\) is the displacement field of shell and \(\mathbf{a}_3\) is the normal to the deformed mid-surface.

The covariant base vectors in the initial and the deformed configurations are

\[
\mathbf{G}_\alpha = \frac{\partial \mathbf{X}}{\partial \zeta^\alpha} = \mathbf{A}_\alpha + \zeta^3 \mathbf{A}_{3,\alpha} \tag{12}
\]

\[
\mathbf{g}_\alpha = \frac{\partial \mathbf{x}}{\partial \zeta^\alpha} = \mathbf{a}_\alpha + \zeta^3 \mathbf{a}_{3,\alpha} . \tag{13}
\]

The corresponding covariant components of the metric tensors in both configurations are

\[
G_{\alpha\beta} = \mathbf{G}_\alpha \cdot \mathbf{G}_\beta : \mathbf{g}_{\alpha\beta} = \mathbf{g}_\alpha \cdot \mathbf{g}_\beta . \tag{13}
\]

3.3 Strain

For measuring the deformation of shell, the Green–Lagrange strain tensor is used:

\[
\varepsilon_{\alpha\beta} = \frac{1}{2} (g_{\alpha\beta} - G_{\alpha\beta}) . \tag{14}
\]

The linearization of (14) will be written as

\[
\varepsilon_{\alpha\beta} = \frac{1}{2} \zeta^3 \kappa_{\alpha\beta} \tag{15}
\]

where the membrane and bending strain tensor are

\[
\varepsilon_{\alpha\beta} = \frac{1}{2} (a_\alpha a_\beta - A_\alpha A_\beta) \]

\[
\kappa_{\alpha\beta} = (A_{\alpha,\beta} A_3 - A_{\alpha} A_{3,\beta}) . \tag{16}
\]

Using (11), the above equation can be written as

\[
\varepsilon_{\alpha\beta} = \frac{1}{2} (A_\alpha \mathbf{u}_\beta + A_\beta \mathbf{u}_\alpha + \mathbf{u}_\alpha \cdot \mathbf{u}_\beta) \]

\[
\kappa_{\alpha\beta} = (A_{\alpha,\beta} A_3 - A_{\alpha} A_{3,\beta} - \mathbf{u}_\alpha \cdot \mathbf{a}_3) . \tag{17}
\]

For small deformation, membrane strain is reduced into the followings

\[
\varepsilon_{\alpha\beta} = \frac{1}{2} (A_\alpha \mathbf{u}_\beta + A_\beta \mathbf{u}_\alpha) \tag{18}
\]

\[
\kappa_{\alpha\beta} = -u_{\alpha\beta} A_3 + \frac{1}{\sqrt{a}} (u_1 \cdot (A_{\alpha,\beta} \times A_2) + u_2 \cdot (A_1 \times A_{\alpha,\beta})) + \frac{A_3 \times A_{a,\beta}}{\sqrt{a}} (u_1 \cdot (A_2 \times A_3) + u_{\beta} \cdot (A_3 \times A_1)) . \tag{19}
\]

3.4 Strain energy

If the shell is linear elastic, the strain energy density can be written as

\[
W(\alpha, \beta) = \frac{1}{2} \left( \frac{E h}{1 - \nu^2} H^{\alpha\beta} \varepsilon_{\alpha\beta} \varepsilon_{\gamma\delta} + \frac{E h^3}{12(1 - \nu^2)} H^{\alpha\beta} \kappa_{\alpha\beta} \kappa_{\gamma\delta} \right) \tag{20}
\]

where \(E\) is Young’s modulus, \(\nu\) is Poisson’s ratio and

\[
H^{\alpha\beta} = u A^{\alpha\beta} A^{\gamma\delta} + \frac{1}{2} (1 - \nu) (A^{\alpha\gamma} A^{\beta\delta} + A^{\alpha\delta} A^{\beta\gamma}) \tag{21}
\]

where the contravariant components of the surface metric tensor

\[
A^{\alpha\delta} A_{\beta\gamma} = \delta^\alpha_\beta \tag{22}
\]

in which \(\delta^\alpha_\beta\) is Kronecker delta and covariant metric tensor is given by

\[
A_{\alpha\beta} = A_\alpha \cdot A_\beta \tag{23}
\]
3.5 Stress resultants
The stress resultants from membrane and bending energies will be
\[ n^{αβ} = \frac{∂W}{∂E^{αβ}} = \frac{Eh}{1 - v^2} \left( H^{αβγδ} ε_{γδ} \right) \]
\[ m^{αβ} = \frac{∂W}{∂K_{αβ}} = \frac{Eh^3}{12(1 - v^2)} \left( H^{αβγδ} K_{γδ} \right) . \]

Explicitly, the above stress resultant matrix can be written as
\[ \begin{pmatrix} n^{αβ} \\ n^{αβ} \end{pmatrix} = \frac{Eh}{1 - v^2} \bar{D} \begin{pmatrix} ε_{γδ} \\ ε_{δγ} \end{pmatrix} \] (26)
\[ \begin{pmatrix} m^{αβ} \\ m^{αβ} \end{pmatrix} = \frac{Eh^3}{12(1 - v^2)} \bar{D} \begin{pmatrix} K_{γδ} \\ K_{δγ} \end{pmatrix} \] (27)

where the rigidity matrix \( \bar{D} \) is
\[ \bar{D} = \begin{bmatrix} A_{11} & vA_{12} + (1 - v)A_{12} \\ A_{12} & A_{22} \end{bmatrix} \text{ sym.} \]
\[ = \begin{bmatrix} (1 - v)A_{11}A_{22} + (1 + v)A_{12}^2 \\ A_{22}A_{12} \end{bmatrix} \]

The stress resultant can be rewritten as
\[ \mathbf{n} = \mathbf{A} \mathbf{ε} ; \quad \mathbf{m} = \mathbf{D} \mathbf{κ} \] (29)
where the vectors \( \mathbf{n}, \mathbf{m} \) are membrane force and bending moment respectively and the matrices \( \mathbf{A}, \mathbf{D} \) are the membrane and bending rigidities.

4. ISOGEOMETRIC FORMULATION

4.1 Kinematics and displacement field
The geometry and displacement field can be defined in the following form:
\[ \mathbf{x} = \sum_{a=1}^{n×m} R_a \mathbf{x}^a ; \quad \mathbf{u} = \sum_{a=1}^{n×m} R_a \mathbf{u}^a \] (30)
where \( R_a \) is the NURBS basis function associated with the control point \( a \), \( \mathbf{x} \) is the position vector of the shell and the displacement vector \( \mathbf{u}^a \) has three components such as
\[ \mathbf{u}^a = \{ \bar{u}_1^a, \bar{u}_2^a, \bar{u}_3^a \} \] (31)
Note that the one-dimensional index \( a \) as a pointer can be expressed as \( a = m(i - 1) + j \) associated with two-dimensional expression and therefore the \( R_a \) of (30) can be interpreted as \( R_{ij}^{pq} \) of (6).

4.2 Strain-displacement relationship matrix
Using (30), the strains of (18) and (19) can be rewritten in the form of the strain-displacement relation matrix \( \mathbf{B} \) as follows
\[ \mathbf{ε} = \sum_{a=1}^{n×m} \mathbf{B}^a \mathbf{u}^a ; \quad \mathbf{κ} = \sum_{a=1}^{n×m} \mathbf{B}^a \mathbf{κ}^a \] (32)
where the sub-matrices of \( \mathbf{B}^a \) and \( \mathbf{B}^a \) are
\[ \mathbf{B}^a = \begin{bmatrix} B_{11}^a & B_{12}^a & B_{13}^a \\ B_{21}^a & B_{22}^a & B_{23}^a \\ B_{31}^a & B_{32}^a & B_{33}^a \end{bmatrix} \] (33)
\[ \mathbf{B}^a = \begin{bmatrix} \frac{∂R_a}{∂x_1} \mathbf{a}_j + \frac{∂R_a}{∂x_2} \mathbf{a}_k \\ \frac{∂R_a}{∂x_1} \mathbf{a}_j + \frac{∂R_a}{∂x_2} \mathbf{a}_k \end{bmatrix} \]
\[ \mathbf{B}^a = \mathbf{B}_{jk} = R_{a,ik} a_j + \frac{1}{\sqrt{a}} \left( \frac{∂R_a}{∂x_1} \cdot (a_j × a_k) + \frac{∂R_a}{∂x_2} \cdot (a_1 × a_{jk}) \right) \]
\[ + \frac{a_j × a_k}{\sqrt{a}} \left( \frac{∂R_a}{∂x_1} \cdot (a_j × a_k) + \frac{∂R_a}{∂x_2} \cdot (a_3 × a_1) \right) \] (34)

4.3 Free vibration analysis
In the absence of external load and damping effects, the dynamic equilibrium equation based on principle of virtual work can be written as
\[ \int_{Ω} \delta \mathbf{ε} \mathbf{A} \, dΩ + \int_{Ω} \delta \mathbf{κ} \mathbf{D} \, dΩ = \int_{Ω} \mathbf{ρ} \delta \mathbf{u} dΩ \] (35)
where \( \mathbf{u} \) is the displacement, \( \mathbf{u} \) is the acceleration, \( \mathbf{p} \) is the density of material and the notation \( \delta \) denotes that the terms are virtual.
The relevant derivation takes place in finite-dimensional subspace to turn the above virtual statement of the problem into a system of algebraic equations. In this study, the subspaces are defined by using the NURBS basis:
\[ \mathbf{u} = \sum_{a=1}^{n×m} R_a \mathbf{u}_a, \quad \mathbf{u} = \sum_{a=1}^{n×m} R_a \mathbf{u}_a \] (36)
where \( n \times m \) is the total number of the control point in the discretized domain and the virtual terms associated with the displacement and acceleration are
\[ \delta \mathbf{u} = \sum_{a=1}^{n×m} R_a \delta \mathbf{u}_a, \quad \delta \mathbf{u} = \sum_{a=1}^{n×m} R_a \delta \mathbf{u}_a \] (37)
Substituting (36) and (37) into (35) yields
\[ \delta u^T[Ku - \bar{M}\bar{u}] = 0. \]  

(38)

Since the virtual displacement \( \delta u \) is arbitrary, the above equation may be written as

\[ Ku - \bar{M}\bar{u} = 0. \]  

(39)

A general solution of (39) may be written

\[ u = \Phi_k e^{i\omega_k}. \]  

(40)

Substituting (40) into (39) yields

\[ [K - \omega_k^2\bar{M}]\Phi_k = 0 \]  

(41)

where \( \Phi_k \) is a set of displacement-type amplitude at the control points otherwise known as the mode vector. \( \omega_k \) is the natural frequency associated with the \( k \)th mode and \( \bar{K} \) and \( \bar{M} \) are global stiffness and mass matrices which contain contributions from element stiffness and mass matrices.

The structural stiffness and mass matrices in (41) can be written as

\[ K = K_{ab} = \bar{K}^{ab} + \bar{K}^{ab} \]

\[ M = M_{ab} = \int_\Omega \bar{R}_a^* \rho \bar{R}_b d\Omega. \]

(42)

(43)

Let the span is assumed to be as an isogeometric element and then the above equation can be written in the knot coordinate system as follows

\[ \prod^{n_{el}}_{e=1} [K^{ab}]^{(e)} = \prod^{n_{el}}_{e=1} \int_{k_e}^{k_{e+1}} [B^a B^b] \det(\eta) d\xi d\eta + \]

\[ \prod^{n_{el}}_{e=1} \int_{k_e}^{k_{e+1}} [B^a G B^b] \det(\eta) d\xi d\eta, \]

(44)

\[ \prod^{n_{el}}_{e=1} [M^{ab}]^{(e)} = \prod^{n_{el}}_{e=1} \int_{k_e}^{k_{e+1}} [R^a_m \bar{m} R_b] \det(\eta) d\xi d\eta \]

(45)

where \( \prod \) is the FE assembly operator (Hughes, 1987), \( n_{el} = n_{span} \times m_{span} \) is the number of elements, \( [k_e k_{e+1}] \) is knot interval for integration in the \( \xi \) and \( \eta \), \( J \) is Jacobian matrix between \( x \) and \( \xi \), \( a, b \) is the basis function number associated with the target element and the matrix \( \bar{m} \) is

\[ \bar{m} = \rho \cdot \begin{bmatrix} h & 0 & 0 \\ 0 & h & 0 \\ 0 & 0 & h \end{bmatrix}. \]

(46)

\[ \lambda_n = w_n r^2 \left( \frac{\rho}{\bar{E}} \right)^{\frac{1}{2}} \]  

(47)

where \( \lambda_n \) is the radius of the circular plate, \( \rho \) is the density of the material and the \( D = E h^3/12(1-v^2) \) is the flexural rigidity of the plate in which \( E \) is the elastic modulus and \( v=0.3 \) is the Poisson ratio.

From numerical test, asymmetric and axisymmetric vibration modes are detected in this test. In the axisymmetric modes, multiple frequencies are obtained. The frequencies obtained from the present shell elements show a very good agreement with the exact solutions in overall modes with rather coarse mesh of 64 isogeometric elements. We illustrate the first fifteen mode shapes in Figure 3. The natural frequencies are calculated in the dimensionless form of (47) and provided in Table 1.
5.2 Elliptical plate

The elliptical plate is analyzed. The geometry of the plate is presented in Figure 4.

![Figure 4. Elliptical plate: (top) Geometry and (bottom) Isogeometric element mesh.](image)

The plate has the aspect ratios $a/b = 4$ and the thickness-span ratio is taken as $2h/b = 0.01$. For analysis, 256 isogeometric elements are used. All units are assumed to be consistent. The results are presented in the dimensionless form

$$
\lambda_n = \frac{w_n \alpha^2 \frac{D}{\rho} \frac{1}{2}}
$$

where $\alpha$ is the radius of the elliptical plates in the $x$ direction, $\rho$ is the density of the material and the $D = E h^3 / 12 (1 - \nu^2)$ is the flexural rigidity of the plate in which $E$ is the elastic modulus and $\nu=0.3$ is the Poisson ratio.

The present solutions are compared with the reference solution produced by Liew (1992) and the FE solutions obtained by using the shell element S9R5 of the ABAQUS and assumed natural strained shell element (Lee, 2001). The natural frequencies and mode shapes of the elliptical plates are presented in Figure 5 and Table 2 respectively.

Free Vibrations of Thin Shells with Isogeometric Approach

From Table 2, it is found to be that the present solutions have an excellent agreement with theoretical solutions. But there are some discrepancies in higher modes with FE solutions. Mostly, two FE reference solutions produces lower natural frequencies compare to theoretical solution (Liew, 1992) and the present isogeometric solutions.

Table 2. The non-dimensionalized natural frequencies $\lambda_n$ of clamped elliptical plate with $a/b=4$.

5.3 Curved fan blade

The vibration of curved fan blade has been frequently studied. Lee et al. (1981) investigated the behaviour of this structure using the Ritz method based on classical thin shallow shell theory in which the different polynomial terms are used. The shell geometry is presented in Figure 6.

The aspect ratio ($a/b=5$), shallowness ratio ($b/R=0.5$) and width-thickness ratio ($b/h=100$) are used in the analysis. The initial location of control point with exact geometry of fan blade section is illustrated in Figure 7.

After 4 times of h-refinement with the orders of basis function $p = q = 5$ in the direction of $x$ and $y$ directions, isogeometric elements is produced and is used to analyze the entire shell. The result is expressed in non-dimensional form:

$$\lambda_n = w_n ab \left(\frac{p}{D}\right)^2$$

where, the flexural rigidity is $D = Eh^3/12(1-\nu^2)$.

The results are compared with the solution obtained by the Ritz method where six and five polynomial terms are used in the $x$ and $y$ directions respectively. From the test, the natural frequencies and the mode shapes are presented in Table 3 and Figure 8.
is also a possibility of using the present isogeometric shell element in the analysis of shells having arbitrary boundary shapes since the present shell element can represent exact geometry of structures using NURBS definition. Finally, the present isogeometric solutions described in this paper are provided as future reference solutions on the structural vibrations of thin plate and shell structures.

**REFERENCES**

(Received February 5, 2014/Accepted May 7, 2014)

**6. CONCLUSIONS**

A thin shell element is developed by using isogeometric concept and used to investigate the behaviours of thin plate and shell structures under free vibration. Numerical examples are carried out to demonstrate the efficiency and accuracy of the present isogeometric shell element. From numerical results, the present isogeometric shell element can produce reliable natural frequencies and associated mode shapes of shells with enough accuracy and it can be used to predict vibrational behaviours of thin plate and shell structures.
