Ganoderma Lucidum Polysaccharides Target a Fas/Caspase Dependent Pathway to Induce Apoptosis in Human Colon Cancer Cells

Zengenni Liang, Yu-Tong Guo, You-Jin Yi, Ren-Cai Wang*, Qiu-Long Hu, Xing-Yao Xiong*

Abstract

Ganoderma lucidum polysaccharides (GLP) extracted from Ganoderma lucidum have been shown to induce cell death in some kinds of cancer cells. This study investigated the cytotoxic and apoptotic effect of GLP on HCT-116 human colon cancer cells and the molecular mechanisms involved. Cell proliferation, cell migration, lactate dehydrogenase (LDH) levels and intracellular free calcium levels ([Ca^{2+}]_i) were determined by MTT, wound-healing, LDH release and fluorescence assays, respectively. Cell apoptosis was observed by scanning and transmission electron microscopy. For the mechanism studies, caspase-8 activation, and Fas and caspase-3 expression were evaluated. Treatment of HCT-116 cells with various concentrations of GLP (0.625-5 mg/mL) resulted in a significant decrease in cell viability (P < 0.01). This study showed that the antitumor activity of GLP was related to cell migration inhibition, cell morphology changes, intracellular Ca^{2+} elevation and LDH release. Also, increase in the levels of caspase-8 activity was involved in GLP-induced apoptosis. Western blotting indicated that Fas and caspase-3 protein expression was up-regulated after exposure to GLP. This investigation demonstrated for the first time that GLP shows prominent anticancer activities against the HCT-116 human colon cancer cell line through triggering intracellular calcium release and the death receptor pathway.

Introduction

Colon cancer, which caused by cellular pathology in the appendix, colon, or in the rectum, is the third most common cancer in the world. Clinically, chemotherapy and radiation are typically used before or after surgery in colorectal treatment. Unfortunately, even with modern intensive medical therapy, a high ratio of recidivations and formation of metastases lead to a low cure rate and scarcely improve long-term survival rate (Luigi et al., 2009). Furthermore, the toxicity produced by chemotherapy inflicts on immune system of cancer patients in the course of treatment.

Currently, compounds from herbaceous plants are recognized as pharmacological agents to inhibit cancer growth and lessen the side effects of radiation and chemotherapy (Chen et al., 2009; Chen et al., 2010). GLP, isolated from Ganoderma lucidum, have been used in East Asian countries to remedy conditions like aging, oxidation, radiation and hypertension for thousands of years (Chen et al., 2009; Pillai et al., 2010; Li et al., 2011). Previous studies have showed that GLP can mediate cytotoxicity in number of cancer cell lines including lung cancer, prostate cancer and breast cancer. Further studies showed that GLP programmed cell death through endothelial growth factor overexpression and tumor angiogenesis inhibition in highly metastatic mouse melanoma B16F10 cells (Sun et al., 2011), through endotoxin-induced intercellular cell adhesion molecule-1 (ICAM-1) upregulation in the neointima in mice (Liu et al., 2010), through cell differentiation and p53 activation in human monocytic leukemia THP-1 cells (Hsu et al., 2011), through activation of mitochondrial signaling pathway in MCF-7 breast cancer cells (Shang et al., 2011). GLP can also boost anticancer immunity by changing lymphocyte phenotype in H22 hepatoma mice (Zhou et al., 2009), by enhancing CD56+ NK-cell cytotoxicity in cord blood (Chien et al., 2004), by promoting the proliferation of B cells in mice (Jiang et al., 2003). Although GLP have been demonstrably effective in fighting cancer by reducing cell growth and boosting cell apoptosis, the anti-cancer effects of GLP have not been reported in human colon cancer cell line HCT-116.

In this study, we isolated and purified polysaccharides from Ganoderma lucidum (Leyss. et Fr.) Karst. Thereafter, HCT-116 cell line was used as a test model to measure the hypothesis that GLP (>10 kDa) affected anticancer effects by MTT assay, migration assay and morphologic observation. We also examined the roles of lactate.
dehydrogenase (LDH), cellular intracellular Ca\(^{2+}\), Fas and caspase cascades in GLP-induced apoptosis in HCT-116 cells.

**Materials and Methods**

**Preparation of GLP**

Slices of *Ganoderma lucidum* (Leyss. et Fr.) Karst. were provided by State Key Laboratory of Sub-health Intervention Technology, State Administration of Traditional Chinese Medicine. GLP were isolated and purified using a procedure as described (Guo, 2012). Crude polysaccharides were gained through deroision, removal of oligosaccharides, hot water extraction, deproteinization, decolorization, concentration under vacuum, and freeze-dried. GLP solution (10 mg/mL in water) was ultrafiltered through 10, 30, and 50 kDa molecular weight cut off membranes (MWCO, Millipore, US), respectively, in an Amicon 8200 stirred cell (Millipore Corporation Bedford, MA). The filtrate (molecular weight of polysaccharides <10 kDa) was freeze-dried, dissolved in high glucose DMEM with 10% FBS to get a stock solution of 10 mg/mL, passed through 0.22 μm filter and stored at 4°C which was prepared for subsequent analysis.

**Cell Culture**

Colon cancer HCT-116 cell line was obtained from Institute of Basic Medical Sciences (Beijing, China). The cells was planted in DMEM medium with high glucose supplemented with 10% FBS in 25 cm\(^2\) tissue culture flasks under a humidified atmosphere of 5% CO\(_2\) at 37°C. The cells with starch (0-10 mg/mL) treatment to each well for 10 min. The absorbance at wavelength of 492 nm was recorded using a microplate reader (MK3, Thermo, USA). Cells with starch (0-10 mg/mL) treatment were subsequently used for this trial.

**Cell viability assay**

HCT-116 cells (3×10\(^5\) cells/well) were seeded onto 96-well plates. After a 12 h recovery period, cells were incubated in fresh medium without or with various concentrations of GLP (0.313, 0.625, 1.25, 2.5 and 5 mg/mL) for 24, 48 and 72 h, respectively, then added 5 mg/mL of MTT solution (20 μL/well) to each well for an additional 4 h. Subsequently removing the supernatant, water-insoluble formazan was dissolved in 150 μL DMSO to each well for 10 min. The absorbance at wavelength of 492 nm was recorded using a microplate reader (MK3, Thermo, USA). Cells with starch (0-10 mg/mL) treatment were used as control. The inhibitory rate was calculated using the following formula: Inhibitory rate (%) = (1 – mean \(A_{\text{experimental}}/\text{mean } A_{\text{control}}\) ) × 100%.

**Wound-healing assay in vitro**

A 24-well plate was spread by monolayer HCT-116 cells and scratched wounds by 10 μL pipette tips. Cells were washed twice with PBS to remove loose cells, and then exposed to 0.625, 1.25, 2.5, 5 and 10 mg/mL of GLP. Following incubation for 48 h, the wounds were photographed under an inverted microscope (BX60, Olympus, Japan). The number of migrant cells was analyzed with Image J software from three visual fields in each group.

**Morphologic observation**

To directly assess the effects of GLP on HCT-116 cells, GLP-induced morphological change was examined by two types of electron microscopes. Transmission electron microscope: GLP-treated cells and untreated cells were trypsinized and suspension-fixed in 1% glutaraldehyde for 2 h. After rinsing with phosphate buffered solution (PBS, pH 7.4), cells were postfixed with 1% osmium tetroxide (OsO\(_4\)) for another 2 h. Dehydration was carried out in an ascending grade of ethanol (50–100%, v/v). Samples were infiltrated with 50% quetol in ethanol for 1 h and additional 1 h incubation with 100% quetol for 6 h, followed by polymerized at 60°C. After 39 h, all groups were cut into ultra-thin sections, stained with 4% uranyl acetate for 10 min. Photographs were taken under a transmission electron microscope (JEM-1230, Tokyo, Japan). Scanning electron microscopy: After GLP inoculation, cells were processed and analyzed as previously described (Wahab et al., 2009). Cells were fixed in 1% glutaraldehyde, post-fixed in 1% OsO\(_4\), dehydrated in a graded of ethanol (50–100%, v/v), critical-point dried, affixed, gold-sputtered and finally viewed by a scanning electron microscope (JSM-6380LV, Tokyo, Japan).

**Lactate Dehydrogenase (LDH) Release Assay**

The apoptotic effect of GLP was examined by measurement of LDH release (Nakagawa et al., 2005). 1.5×10\(^5\) cells per well were plated in 24-well cell culture plate, followed by overnight incubation. Supernatants were collected and added in a black 96-well culture plates (200 μL per well) after cells were exposed to increasing concentrations of GLP (1.25, 2.5 and 5 mg/mL) for 48 h. LDH release was measured using LDH cytotoxicity assay kit (Beyotime, China) as per the manufacturer’s instructions. Absorbance at a wavelength of 450 nm in each well was determined using an enzyme linked immunoassay instrument.

**Detection of Intracellular Ca\(^{2+}\) level**

GLP-treated cells were rinsed twice with PBS, resuspended in Hanks’ buffer (pH 7.4) containing 0.2% bovine serum albumin (BSA), and treated with 10 μmol/L of fura-2 acetoxyethyl ester (Fura-2 AM) at 37°C for 30 min in the dark. Cells were then harvested, washed three times and resuspended in hanks’ buffer. The fluorescence were monitored by recording in the ratio mode excitation wavelength at 340/380 nm and 510 nm emission wavelength using a varioskan flash (Thermo, USA). Maximal fluorescence (Fmax) was obtained in the presence of 10% Triton X-100 (final concentration 0.1%) and followed by minimum fluorescence (Fmin) with 5 mmol/L of EDTA. Intracellular Ca\(^{2+}\) was calculated from the fluo-2 fluorescence intensity using the equation: \([\text{Ca}^{2+}] = K_d \cdot (F - F_{\text{min}})/(F_{\text{max}} - F)\), where \(K_d\) of fluo-2 for Ca\(^{2+}\) is 224 nM (Grynkieiewicz et al., 1985; Hirst et al., 1999).

**Detection of caspase-8 Activity**

The caspase-8 activity was determined using the caspase-8 activity kit (Beyotime, China) according to the manufacturer’s recommendations. Briefly, cells (1×10\(^6\) cells/well) were exposed to 0, 2.5 and 5 mg/mL.
The yield of crude polysaccharides was about 3.08%.

Isolation and structural analysis

 Results

Isolation and structural analysis

The yield of crude polysaccharides was about 3.08%.

Western blot analysis

Cells were treated with 5 mg/mL GLP for different time points (0, 12, 24, 36, and 48 h). After washing three times in PBS, cells were lysed in RIPA lysis buffer (Applygen, China) on ice for 30 min. The protein concentration was determined utilizing the Bradford assay (Bio-Rad, CA). Subsequently, proteins were separated by 10%-12% SDS-PAGE, electrotransferred to polyvinylidene fluoride (PVDF) membranes (Millipore, US), and blocked in 5% non-fat dehydrated milk. The membranes were incubated with β-actin (1:4000, Proteintech, US), Fas (1:1000, Proteintech, US), caspase-3 (1:500, Proteintech, US), caspase-8 (1:500, Proteintech, US), and caspase-9 (1:500, Proteintech, US) primary antibodies, respectively, followed by secondary antibodies (1:3000, Santa Cruz Biotechnology, US). The signal was detected as described (Suresh et al., 2013).

Statistical Analysis

All experiments were performed in triplicate and the data were expressed as mean ± S.D. Statistical analysis was performed using the statistical software SPSS 18.0, with highly significance at P<0.01.

Results

Isolation and structural analysis

The yield of crude polysaccharides was about 3.08%.
uniform cellular distribution and numerous microvilli on their surface. In GLP-treated cells, 2.5 and 5 mg/mL of GLP were significant changes in cell morphology that corresponded to a typical cellular surface morphology of apoptosis, including cell membrane blebbing, cellular density and microvilli reduction, apoptotic body formation (as shown in white arrow) (Figure 2).

Transmission electron microscopy

Induction of apoptosis was also inspected using transmission electron microscopy. Control cells had a well regular cell shape, many microvilli protruding from their surfaces, homogeneous chromatin distribution (Figure 3A), rough endoplasmic reticula and healthy-looking mitochondrion (arrow) (Figure 3B). On the contrary, 5 mg/mL GLP lead to irregular cell shape, a decreased microvillar density, mitochondria swelling, chromatin concentration and marginalization (arrow) (Figure 3C), cytoplasm vacuolization and apoptotic bodies formation (arrow) (Figure 3D). Treatment with 10 mg/mL GLP induced collapse of plasma membrane, resulting in cell decomposition and death (Figure 3E).

GLP promoted LDH release and intracellular [Ca²⁺] increase

The aim was to determine whether GLP-induced apoptosis was involved in these crucial events in HCT-116 cells. LDH activity of culture medium had a dose-dependent increase (71.66 ± 11.47, 97.65 ± 5.87 and 144.13 ± 11.00 versus 49.77 ± 2.15 in control group, P<0.01) at the concentrations of GLP (1.25, 2.5 and 5 mg/mL) (Figure 4A). The intracellular Ca²⁺ levels, in contrast to control, were also significantly promoted after incubation with GLP for 24 h (P<0.01) (Figure 4B).

GLP activated caspase-8 and altered abundance of apoptosis-associated protein

We next investigated the possible mechanism of GLP-induced apoptosis by Western blot experiments. As shown in Figure 5A, 5 mg/mL of GLP significantly enhanced caspase-8 activity compared to control (P<0.01). The result suggests that the activation of caspase-dependent apoptosis signaling pathways might be involved in GLP-induced apoptosis in human colon cancer cells. In western blot assay, we found that the levels of caspase-3 and Fas proteins were up-regulated in HCT-116 cells cultured in the solution with 5 mg/mL GLP at 12 h-48 h. We also found a direct correlation between the levels of caspase-3 and Fas proteins and incubation period of GLP (Figure 5B).

Discussion

Due to serious side effects of chemotherapy in cancer patients, we require new therapeutic strategies to be found. Polysaccharides from herb plants especially mushroom have been proven to be effective anti-tumor compounds with no toxicity (Shi et al., 2013; Giavasis, 2014; Ning et al., 2014). It has been reported that GLP exert strong anti-tumor effect when the molecular weight was larger than 1×10⁴ (Liu et al., 2010). The reasons may be that polysaccharides with molecules weight in the range have not only a good dissolubility in water but also a relative complex structure (Dai et al., 2013). GLP have been found to possess anticancer activity without toxicity, but the molecular mechanisms involved remain unresolved. We previously identified that GLP and 5-fluorouracil (5-FU) contributed synergistically to inhibit growth and induce apoptosis against human colon cancer cells in vitro. The effect was associated with dose-response relationship of GLP exposure (Liang et al., 2012).

In our current study, high molecular weight GLP larger than 10 kDa was obtained by ultrafiltration and observed its anti-cancer effects on human colon cancer HCT-116 cells. The data showed a range of doses between 0.625 and 5 mg/mL GLP had a robust dose and time-dependent inhibitory effects on proliferation in HCT-116 cells (Figure 1). Considering the effect of osmotic pressure produced by GLP (0.313-5 mg/mL), the polysaccharide starch was applied to control the efficacy of GLP suppression in

GLP altered abundance of apoptosis-associated protein](image)
HCT-116 cells. The results also showed that starch (0.313 -10 mg/mL) dose-dependently promoted cell growth, suggesting the osmotic pressure in the cell culture with these concentrations of GLP did not markedly induce cell death. Cell migration is a critical process for sustained maintenance and development of every type of cancer cells (Condeelis and Pollard, 2006). Especially, malignant cancer cells put into use their own migratory capacity to invade adjacent healthy tissues and the vasculature, then ultimately to inflict devastating organizer destruction (Yamaguchi and Condeelis, 2007). Thus, limitation of this process is a novel therapeutic strategy for controlling tumor growth and deterioration. In the present study, we reported that GLP mediated dose-dependent inhibitory effects on cell migration of human colon cancer HCT-116 cells (P<0.01). The data showed that GLP may cause antitumor effects by suppression cell growth and migration in HCT-116 cells. Cell apoptosis triggered by most of cancer chemopreventive agents and anticancer drugs is an essential process in prevention of tumor promotion (Núñez et al., 2010). It is commonly measured by the increase in release of LDH, TUNEL staining, intracellular Ca²⁺ concentration, cytoplasm condensation, DNA and nuclear fragmentation (Liu et al., 2006). Under SEM and TEM observation, vacuoles, apoptotic bodies, chromatin margination and cell degradation appeared in GLP -incubated cells (Figure 2 and Figure 3). As further proof of the apoptotic effects of GLP, LDH release and intracellular Ca²⁺ concentration were also determined. The permeabilization of the plasma membrane is a key signature for apoptotic cells, which can be quantified in tissue culture settings by measuring the release of the intracellular enzyme LDH (Sun et al., 2013). As an important messengers and a key regulator, Ca²⁺ can control apoptosis in response to a variety of pathological conditions from external and internal environment though a wide range of Ca²⁺ sensitive factors that are compartmentalized in various intracellular organelles including the mitochondria, ER and cytoplasm. GLP has been reported to promote calcium levels in the brain of D-gal-treated mice (Li et al., 2011). In this study, GLP also induced apoptosis by promoting the release of LDH (Figure 4A) and increased the level of intracellular Ca²⁺ (Figure 4B). These results clearly indicated that GLP significantly induced apoptosis in HCT-116 cells. Next, we investigated the possible mechanisms of GLP-mediated apoptosis. Intrinsic (mitochondrial) and extrinsic (death receptor) apoptotic pathways are two major ways to stimulate cell apoptosis. In extrinsic pathway, ligand-bound death receptors such as Fas and TRAIL receptors have been well characterized to be a crucial regulator, which mediate activation of caspase cascades in some types of cancer cells (Sayers, 2011). It is demonstrated that caspase-3/8 activation is physically associated with the signaling complex during Fas-induced apoptosis (Mandal et al., 2005). In addition to the caspase-dependent pathway, cell apoptosis also has been reported to be stimulated via caspase-independent pathway (Liu and Chang, 2011). In this study, GLP activated caspase-8 (Figure 5A) and up-regulated caspase-3 (Figure 5B), indicating that caspase-dependent pathway is related to GLP-induced apoptosis. It also increased the level of Fas protein (Figure 5B). Additionally, the addition of GLP treatment is attributed to enhanced active caspase-8 signaling and levels of Fas or caspase-3. These findings implied that GLP-induced apoptosis might activate Fas-mediated caspase-dependent pathway in HCT-116 cells. Interestingly, we found cytosolic Ca²⁺ was released during the cell apoptosis induced by GLP, which is believed to be a key activation signal in mitochondrial signaling pathway. Therefore, whether mitochondrial pathway participates in GLP-stimulated apoptosis remains need further investigation. In conclusion, the present study offers a novel insight into the cytoxicity and apoptosis of GLP in human colon cancer HCT-116 cells, suggesting that these findings provide potential perspectives for further research on pharmacology of GLP as a possible candidate for the cancer prevention or treatment of colon cancer.
