show the isosbestic point at 308 nm indicating that TMP is converted into the complex. TMP carbonyl stretching vibration at 1705cm⁻¹ is little shifted but a new broad band appeared at 1040-1110cm⁻¹ suggesting that carbonyl oxygen of TMP does not strongly interact with BF₃. Figure 4 shows the fluorescence spectra of TMP in the absence and presence of BF₂OEt₂ at room temperature. The large Stokes shifts \( \Delta \lambda = \lambda_{\text{max}}' - \lambda_{\text{max}} \) (the fluorescence maximum) - \( \lambda_{\text{max}} \) (the absorption maximum) are observed as the concentration of BF₂OEt₂ is increased. The position of \( \lambda_{\text{max}} \) (425 nm) is considerably shifted towards the longer wavelength (475 nm) and the fluorescence intensity is gradually increased.

The results, which are reminiscent of the behavior of simpler carbonyls, can be interpreted in terms of the energy level disposition of the \( \psi(n, \pi^*) \) state relative to the lowest energy \( \psi(n, \pi^*) \) state. In TMP, the \( \psi(n, \pi^*) \) state lies below \( \psi(n, \pi^*) \) state and \( \psi(n, \pi^*) \) \( \rightarrow \psi(n, \pi^*) \) intersystem crossing is efficient due to the relative strong \( \psi(n, \pi^*) \) \( \rightarrow \psi(n, \pi^*) \) spin-orbit coupling. In the complex, coordination of the nonbonding electrons of the \( \alpha, \beta \)-unsaturated carbonyl group results in lowering the \( \psi(n, \pi^*) \) energy level as well as the redistribution of the orbital electron densities and the \( \psi(n, \pi^*) \) state becomes higher than the \( \psi(n, \pi^*) \) state. The energy level ordering is reversed so that the fluorescence becomes competitive with intersystem crossing. Kearns et al. expected \( \psi(n, \pi^*) \) \( \rightarrow \psi(n, \pi^*) \) transition to be \( 10^2 \) \( \times \) more efficient than \( \psi(n, \pi^*) \) \( \rightarrow \psi(n, \pi^*) \) transitions.¹¹

Unlike the BF₂-catalyzed photodimerization of coumarin and cinnamic esters in which the reactivity and stereoselectivity are enhanced, an unusual Lewis acid effect was observed in the photodimerization of TMP. Increasing BF₂OEt₂ concentration decreases the quantum yield of dimerization. The kinetics and mechanism of the BF₂-catalyzed reaction are currently under investigation to elucidate the reactive species and exact reason of the abnormal effect. The complexity, however, should substantially change both the ground and excited-state energies and the energy level ordering and thus account for the reactivity change observed in the presence of BF₂OEt₂.

A Novel Method for Conversion of Lactones into ω-Bromoalkyl Sulfides

Sunggak Kim*, Ki Jeong Moon, and Sung Soo Kim

Department of Chemistry, Korea Advanced Institute of Science and Technology, Seoul 130-012

Received February 27, 1989

We have previously reported a novel method for direct conversion of carboxylic acids and carboxylic esters into S,S'-diphenyl acetics and phenyl sulfides with thexylophenylthioborane.¹² During the course of mechanistic studies, it has been found that lactones can be converted into ω-haloalkyl phenyl sulfides with phenyl thexylbromothioborinate and dibromoborane-dimethyl sulfide in the presence of zinc halide. As far as we are aware, this is the first example in which carbonyl and alkoxy group are simultaneously transformed to the sulfide and the halo group, respectively, by an one-pot procedure.

An equimolar mixture of phenyl thexylbromothioborinate and dibromoborane-dimethyl sulfide was prepared by the reaction of thexylbromoborane-dimethyl sulfide with boron tribromide in dichloromethane followed by treatment with

$^a$The reaction was carried out with 3.0 equiv of the reagent in the presence of 1.0 equiv of zinc bromide in dichloromethane at room temperature for 24 h. $^b$Method A: phenyl thexylbromothioborinate/dibromoborane-dimethyl sulfide. Method B: n-butyl thexylbromothioborinate/dibromoborane-dimethyl sulfide. $^c$Isolated yields of ω-haloalkyl sulfides. The numbers in parenthesis indicate the yield of the corresponding bromides. $^d$1.0 Equiv of zinc iodide was used.

0.5 equiv of bis(phenylthio) lead$^3$. The reagent in dichloromethane can be stored in a refrigerator for several weeks without little decomposition. An equimolar mixture of n-butyl thexylbromothioborinate and dibromoborane-dimethyl sulfide was prepared in a similar manner using bis(n-butylthio) lead.

After much experimentation to find out an optimum condition, it was found that the reaction of ε-caprolactone with 3.0 equiv of an equimolar mixture of phenyl thexylbromothioborinate and dibromoborane-dimethyl sulfide in the presence of 1.0 equiv of zinc iodide in dichloromethane at room temperature for 18 h gave 6-hexylxethyl phenyl sulfide in 71% yield together with a small amount of 6-bromohexyl phenyl sulfide. The use of zinc bromide gave exclusively 6-bromohexyl phenyl sulfide in 72% yield under the similar conditions. 2-Methyl ε-caprolactone was converted into 6-bromo-2-methylhexyl phenyl sulfide in 65% yield, indicating nucleophilic cleavage of the alkyl-oxygen bond by bromide anion. The ring opening of lactones by the nucleophilic cleavage of the alkyl-oxygen bond has been previously reported. The examples include iodotrimethylsilane$^4$, sodium phenyl selinite$^5$, aluminum halide/thiol$^6$, and boron tribromide$^7$ which allow the conversion of lactones into synthetically useful ω-functionalized carboxylic acids.

Table 1 includes some experimental results and illustrates the applicability, efficiency, and the scope of the method. The present method works well with 8-membered and macrocyclic lactones. However, this method reaches a limit with γ- and δ-lactone. For instance, δ-valerolactone produced 5-bromopentyl phenyl sulfide in 25% yield along with several byproducts. The similar result was obtained with γ-butyrolactone.

The reaction was also carried out with an equimolar mixture of n-butyl thexylbromothioborinate and dibromoborane-dimethyl sulfide. The reaction proceeded smoothly, yielding ω-bromoalkyl n-butyl sulfides. The scope and limitations were almost identical with phenyl thexylbromothioborinate and the results are summarized in Table 1.

2. The structure of the reagent was incorrectly assigned into a mixture of thexylphenylthioborane and boron tribromide-dimethyl sulfide. It was turned out to be a mixture of phenyl thexylbromothioborinate and dibromoborane-dimethyl sulfide. The proof for its structure determination will be reported in detail as a full paper.
3. To a solution of thexylbromoborane-dimethyl sulfide (5.93 g, 25 mmol) in dichloromethane (80 ml) under nitrogen at room temperature was added boron tribromide (6.25 g, 25 mmol). The reaction mixture was stirred for 1 h, followed by the addition of bis(phenylthio) lead (5.3 g, 12.5 mmol). After being stirred for 0.5 h, precipitated lead bromide was removed and the concentration of the reagent was adjusted to 0.25 M solution by adding dichloromethane.
