Two new carborane complexes containing closo- or nido- carborane diphosphine ligands with the formula: complex [Hg(7,8-(PPh2)2-7,8-C2B10H10)]2 CH2Cl2 (1) and [Ag(μ-Cl)(1,2-(PPr2)-1,2-C2B10H10)]2 (2) have been synthesized and characterized by elemental analysis, 1H and 13C NMR spectroscopy and X-ray structure determination. The X-ray structure analyses revealed that the carborane diphosphine ligand was degraded from closo-1,2-(PPh2)2-1,2-C2B10H10 to nido-[7,8-(PPh2)2-7,8-C2B10H10] in complex 1, while the closo nature of the starting ligand 1,2-(PPr2)-1,2-C2B10H10 was retained in complex 2. In either of the two complexes, the carborane diphosphine ligand was coordinated bidentately to the Hg(II) or Ag(I) center through its two phosphorus atoms, therefore forming a five-member chelating ring between the carborane ligand and the metal center. The coordination geometry of the metal atom is distorted tetrahedron formed by P4 unit in complex 1 and P4Cl2 unit in complex 2, respectively.

Key Words: Synthesis and crystal structure, Hg(II) and Ag(II) complexes, [7,8-(PPh2)2-7,8-C2B10H10]2, 1,2-(PPr2)-1,2-C2B10H10

Introduction

Bidentate ligands have played an important role in the development of catalytic applications of metal organic complexes.1 One of the important fundamentals for these catalysts is that two cis positions of the metal center are available to perform the reaction, and bidentate phosphines have already been demonstrated to be very convenient for this sort of catalysis.2 The o-carborane diphosphine derivative 1,2-bis(phenylphosphanyl)-1,2-dicarba-closo-dodecaborane was first reported by Alexander and Schroeder in 1963.3 Because the two phosphorus atoms bonded to the two adjacent carbon atoms of the o-carborane are fixed by the geometry of the carborane skeleton in an eclipsed conformation at cis positions, stable complexes can be formed through a five-member chelating ring between the ligand and a metal atom, making these types of diphosphines ligands being widely studied in coordination chemistry.

The reactions of the closo ligand 1,2-(PPh2)2-1,2-C2B10H10 with transition metal compounds have been intensely studied,4-11 and the results reported previously showed that the polarity of the solvent used in the reactions played an very important role in the degradation process of the closo carborane diphosphine ligand. Recently, our group have also interested in carborane diphosphine ligands and reported some complexes containing closo carborane diphosphine 1,2-(PPh2)2-1,2-C2B10H10, 1,2-(PPr2)2-1,2-C2B10H10 and nido carborane diphosphine [7,8-(PPh2)2-7,8-C2B10H10]2,12,13 in which the CuI complex of 1,2-(PPh2)2-1,2-C2B10H10 show some catalytic activity for the amination of iodobenzene with aniline.12a Very recently, with the consideration that the Hg complex of carborane organophosphorus-substituents ligands is still very rare,14 we investigated the reactions of 1,2-(PPh2)2-1,2-C2B10H10 with mercury(II) compounds.15 Here, we present one Hg complex [Hg(7,8-(PPh2)2-7,8-C2B10H10)]2 CH2Cl2 (1) and one silver(I) complex [Ag(μ-Cl)(1,2-(PPr2)-1,2-C2B10H10)]2 (2) based on two closo carborane diphosphine ligands (1,2-(PPh2)2-1,2-C2B10H10 and 1,2-(PPr2)-1,2-C2B10H10) with different steric effects, for which the synthesis, characterization and crystal structures will be described in this paper.

Experimental

Materials and Methods. All the reactions were carried out under an atmosphere of dry oxygen-free dinitrogen. Dichloromethane, ethanol, and n-hexane were dried with appropriate drying agents and distilled under dinitrogen prior to use. 1,2-(PPh2)2-1,2-C2B10H10 and 1,2-(PPr2)-1,2-C2B10H10 were synthesized according to a literature procedure.5,16 All chemicals were purchased and used as received. Infrared spectra was measured on a Nicolet-460 FT-IR spectrometer in the range 400-4000 cm−1 as KBr pellets. Elemental analysis (C, H) was performed with a Perkin-Elemer 2400 II Elemental Analyzer.

Synthesis

[Hg(7,8-(PPh2)2-7,8-C2B10H10)]2 CH2Cl2 (1): 1,2-(PPh2)2-1,2-C2B10H10 (102.4 mg, 0.2 mmol) and HgCl2 (27.1 mg, 0.1 mmol) was mixed in 10 mL CH2CN. The mixture was refluxed for 5 h under the protection of N2, and then the colorless solid formed was filtrated off and dried in vacuum (71.2 mg, 55.2%). The crystal suitable for X-ray diffraction
was obtained from a dichloromethane-n-hexane solution. FT-IR iKBr (cm⁻¹): 2958s, 2578m, 1611s, 1437m, 1095m, 748m, 694s, 493m. ¹H NMR (400.15 MHz, CDCl3): δ 7.192-7.897 ppm (40H); ¹³C NMR (100.62 MHz, CDCl3): δ 128.6-135.9 ppm (48C), δ 76.1-78.5 ppm (4C). The mixture was refluxed for 5 h under the protection of N₂, and concentrated to 5 mL, and then 20 mL n-hexane was added to precipitate the solid. Yield: 85.5 mg, 56.3%. The crystal suitable for X-ray diffraction was grown from a dichloromethane-n-hexane solution. FT-IR iKBr (cm⁻¹): 2999m, 2961s, 2921m, 2873m, 2851m, 2577s, 1631m, 1460s, 1386m, 1229s, 1173m, 1095m, 808s, 785m, 685s, 493m.

Crystallography. The colorless crystals of complexes 1 and 2 were selected for the diffraction analysis. The collections of intensity data were carried out on a Bruker Smart-1000 CCD diffractometer, using graphite-monochromatized Mo-Kα radiation (λ = 0.71073 Å) at 298(2) K. The structures were solved by direct methods and expanded using Fourier difference techniques with SHELXTL-97 program package. The non-hydrogen atoms were refined anisotropically by full-matrix least-squares calculations on F². All H atoms were located from Fourier maps and were refined isotropically. The crystallographic data for the two complexes were summarized in Table 1 and the selected bond lengths and angles of complexes 1 and 2 were shown in Table 2.

The CIF tables of 1 and 2 have been deposited at the Cambridge Crystallographic Data Centre with the deposition numbers CCDC 891541 and 891542, respectively. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: (+44) 1223 336033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk].

The strong polarity solvent can make the closo skeleton of the carborane cage be degraded to nido form, while the closo skeleton can be retained when weak polarity solvent was used in the reaction. Based on these results, we investigated the reactions of 1,2-(PPh₃)₂-1,2-C₆B₁₀H₁₀ with AgCl in CH₂Cl₂ and 1,2-(PPh₃)₂-1,2-C₆B₁₀H₁₀ with AgCl in CH₂Cl₂ under the reflux condition, respectively, and obtained two complexes containing closo- or nido- carborane diphosphate ligands with the formula [Hg(7,8-(PPh₃)₂-7,8-C₆B₁₀H₁₀)]⁻(CH₂Cl₂)Cl⁻ [Ag₂(μ-Cl)(1,2-(PPh₃)₂-1,2-C₆B₁₀H₁₀)]⁻(Scheme 1).

Both of the two complexes have been characterized by FT-IR, ¹H and ¹³C NMR spectroscopy. The IR spectra of these two complexes were very similar to each other. The absorption at 2958 (1) and 2999 (2) cm⁻¹ may be attributed to the ν(C=H) stretching vibration of benzene ring and isopropyl group, and the characteristic absorptions of terminal B-H vibrations are at about 2570 cm⁻¹ for 1 and 2, which drop in the normal range from 2625 to 2450 cm⁻¹.¹⁸ The peak at about 1100 cm⁻¹ is the absorption of ν(C(Carborane cage)-P). This is lightly shifted in keeping with phosphorus coordination to the 1,2-C₆B₁₀H₁₀ moiety. The ¹H NMR (400.15 MHz) showed a resonance at ca. −2.10 ppm which can be assigned to the bridge H atoms of B-H-B in complex 1. The resonance at about 130 ppm, 21-30 ppm and about 77 ppm in the ¹³C NMR spectra (100.63 MHz) for these two complexes can be assigned to the carbon atom of the benzene ring, the isopropyl group and the carborane cage, respectively.

Description of the Structure. Crystal structures of these two complexes are shown in Figures 1 and 2, respectively. Selected bonds and angles are given in Table 2. Complex 1 contains four formula units in the unit cell and the solvent CH₂Cl₂, and crystallizes in the monoclinic space group.
Two New closo- or nido- Carborane Diphosphine Complexes

P2(1)/n. The central Hg atom is coordinated to four P atoms coming from two nido carborane diphosphine anions [7,8-(PPh2)2-7,8-C2B10H10]. The geometry at the Hg atom is a distorted tetrahedron, and the angles around Hg (Table 2) deviate much from the values for a regular tetrahedron coordination mode. The distances of the four Hg-P bonds are almost equal to each other, and the average value of 2.575 Å is slightly longer than those in the reported Hg complex [HgCl(PPh3){7,8-(PPh2)2-7,8-C2B10H10}],15 which can be attributed to the steric effect of the two ligands. The angles of P(1)-Hg(1)-P(2) (79.63(8)) and P(3)-Hg(1)-P(4) (78.19(9)) are slightly smaller than the value of 82.74(5) in [HgCl(PPh3){7,8-(PPh2)2-7,8-C2B10H10}]. As for the other parameters in complex 1, such as the distances of P-Cc and Cc-Cc as listed in Table 2, no noticeable differences have been found on comparison to those in the above complex.

The complex 2 crystallizes in the monoclinic C2/m space group (Fig. 2) and contains two formula units in the unit cell. It is composed of two same units [Ag(1,2-(PipiPr2)2-1,2-C2B10H10)] bridged by two Cl atoms. The Ag atom is coordinated by two P atoms of the Ppipr2 group and two Cl anions to complete the distorted tetrahedral configuration, which can be proved by the bond angles around the Ag atom (Table 2). The Ag1-P1 and Ag1-C11 distances are 2.4717(12) and 2.6220(19) Å, respectively, which are basically consistent with the corresponding bond lengths in [Ag(µ-Cl)(1,2-(PPh2)2-1,2-C2B10H10)].19 The dihedral angle between the planes through the atom groups P1-Ag1-P1fake#1 and Cl1-Ag1-C11#1 is 86.85°, indicating that these two planes are almost perpendicular each other. The C(1)-C(2) bond distance in complex 2 is 1.69(2) Å, which are slightly shorter than 1.720 Å in the free ligand.16 Comparison of the configuration of the closo carborane diphosphine ligand in complex 2 with that in the free 1,2-(PPh2)2-1,2-C2B10H10 ligand reveals differences. In the free ligand the P(1)-C(1)-C(2) torsion angle is 10.6(3)°,16 while this angle in complex 4 is only 0.1(5)°. This data indicates that coordination of the ligand to Ag(I) alters the symmetry of the ligand, making the symmetry of the ligand in the complex 2 closely approach C2v.

Symmetry transformations used to generate equivalent atoms:

#1: x, -y, z #2: -x+1, -y, -z+1

In summary, we have obtained two new carborane diphosphine complexes containing closo or nido diphosphine ligand by using two types of closo carborane diphosphine

ligands with different steric effects in different polar solvent, in which the closo carborane skeleton was degraded to nido form in complex 1 and that was retained in complex 2. The present result can further confirm the fact that the polarity of the solvent has obvious influence on the structure of the complexes formed, despite of the different steric effect brought by the carborane diphosphine ligand.
