STABILITY OF MULTIPLICATIVE INVERSE
FUNCTIONAL EQUATIONS IN THREE VARIABLES

Eun Hwi Lee

Abstract. In this paper, we prove stabilities of multiplicative functional equations in three variables such as

\[ r\left(\frac{x + y + z}{3}\right) - r(x + y + z) = \frac{2r\left(\frac{x + y}{2}\right)r\left(\frac{x + z}{2}\right)}{r\left(\frac{x + y}{2}\right)r\left(\frac{x + z}{2}\right) + r\left(\frac{x + z}{2}\right)r\left(\frac{z + x}{2}\right)} + r\left(\frac{x + y}{2}\right)r\left(\frac{z + x}{2}\right) \]

and

\[ r\left(\frac{x + y + z}{3}\right) + r(x + y + z) = \frac{4r\left(\frac{x + y}{2}\right)r\left(\frac{z + x}{2}\right)}{r\left(\frac{x + y}{2}\right)r\left(\frac{z + x}{2}\right) + r\left(\frac{x + y}{2}\right)r\left(\frac{z + y}{2}\right)} + r\left(\frac{x + y}{2}\right)r\left(\frac{z + y}{2}\right). \]

1. Introduction

In 1940, Ulam [16] proposed the Ulam stability problem of additive mappings:

Let \( G_1 \) be a group and let \( G_2 \) be a metric group with a metric \( d(\cdot, \cdot) \). Given \( \epsilon > 0 \), does there exist a \( \delta > 0 \) such that if a mapping \( h : G_1 \to G_2 \) satisfies the inequality

\[ d(h(xy), h(x)h(y)) < \delta \]

for all \( x, y \in G_1 \), then there exists a homomorphism \( H : G_1 \to G_2 \) with \( d(h(x), H(x)) < \epsilon \) for all \( x \in G_1 \)?

In 1941, Hyers [6] answered the Ulam’s question for the case of the additive mapping on the Banach spaces.

Let \( G_1 \) and \( G_2 \) are Banach spaces. Assume that a mapping \( f : G_1 \to G_2 \) satisfies the inequality

\[ ||f(x + y) - f(x) - f(y)|| \leq \epsilon \]
for all $x, y \in G_1$. Then the limit $g(x) := \lim_{n \to \infty} f\left(\frac{2^n x}{2^n}\right)$ exists for all $x \in G_1$ and $g$ is the unique additive mapping satisfying

$$||f(x) - g(x)|| \leq \varepsilon$$

for all $x \in G_1$.

In 1978, Th. M. Rassias [13] generalized the above result of an approximation involving a sum of norms; Let $G_1$ be a vector space and $G_2$ a Banach space. Assume that a mapping $f : G_1 \to G_2$ satisfies

$$||f(x + y) - f(x) - f(y)|| \leq \varepsilon(||x||^p + ||y||^p)$$

for all $x, y \in G_1$, $\varepsilon > 0$ and $p < 1$. Then the limit $g(x) := \lim_{n \to \infty} f\left(\frac{2^n x}{2^n}\right)$ exists for all $x \in G_1$ and $g$ is the unique additive mapping satisfying

$$||f(x) - g(x)|| \leq \frac{2\varepsilon}{2 - 2^p}||x||^p$$

for all $x \in G_1$.

During the last two decades a number of papers and research monographs have been published on various generalizations and applications of the generalized Hyers-Ulam stability to a number of functional equations and mappings (see [1]-[16]). P. Găvruţa [4] provided a further generalization of Th. M. Rassias’ Theorem.

In this paper, we investigate stabilities of another type functional equations in three variables such as

$$r\left(\frac{x + y + z}{3}\right) - r(x + y + z)$$

$$= 2r\left(\frac{x+y}{2}\right)r\left(\frac{y+z}{2}\right)r\left(\frac{z+x}{2}\right)$$

and

$$r\left(\frac{x + y + z}{3}\right) + r(x + y + z)$$

$$= 4r\left(\frac{x+y}{2}\right)r\left(\frac{y+z}{2}\right)r\left(\frac{z+x}{2}\right).$$

Since $\frac{1}{x}$ is a solution of these equations, these called multiplicative inverse functional equations in three variables. Also the solution of equation (1.1) and (1.2) are called multiplicative inverse mappings. Note
that reciprocal difference functional equations

$$r\left(\frac{x+y+z}{3}\right) - r(x+y+z) = \frac{2r(x)r(y)r(z)}{r(x)r(y)+r(y)r(z)+r(z)r(x)}$$

and reciprocal adjoint functional equations in three variables

$$r\left(\frac{x+y+z}{3}\right) + r(x+y+z) = \frac{4r(x)r(y)r(z)}{r(x)r(y)+r(y)r(z)+r(z)r(x)}.$$  

are similar types with multiplicative functional equations in three variables. Stabilities of reciprocal difference functional equation and the reciprocal adjoint functional equation in two variables was proved by K. Ravi, J. M. Rassias and B. V. Senthil Kumar [15]. And Y. W. Lee and G. H. Kim [14] extend these equations to m-variables. But we investigate stabilities of another type functional equations in three variables.

### 2. Stabilities

Define for all $x, y, z$ in $R$,

$$D_r(x, y, z) = r\left(\frac{x+y+z}{3}\right) - r(x+y+z)$$

$$= \frac{2r\left(\frac{x+y}{2}\right)r\left(\frac{y+z}{2}\right)r\left(\frac{z+x}{2}\right)}{r\left(\frac{x+y}{2}\right)r\left(\frac{y+z}{2}\right)+r\left(\frac{y+z}{2}\right)r\left(\frac{z+x}{2}\right)+r\left(\frac{z+x}{2}\right)r\left(\frac{x+y}{2}\right)}$$

and

$$E_r(x, y, z) = r\left(\frac{x+y+z}{3}\right) + r(x+y+z)$$

$$= \frac{4r\left(\frac{x+y}{2}\right)r\left(\frac{y+z}{2}\right)r\left(\frac{z+x}{2}\right)}{r\left(\frac{x+y}{2}\right)r\left(\frac{y+z}{2}\right)+r\left(\frac{y+z}{2}\right)r\left(\frac{z+x}{2}\right)+r\left(\frac{z+x}{2}\right)r\left(\frac{x+y}{2}\right)}.$$  

**Theorem 1.** Let $X$ and $Y$ be spaces of non-zero real numbers. Assume that $f : X \to Y$ satisfies the functional inequality

$$|D_f(x, y, z)| \leq \phi(x, y, z)$$  

for all $x, y, z \in X$, where $\phi : X^3 \to Y$ is a function such that for all $x, y, z \in X$

$$\Phi(x, y, z) := \sum_{i=0}^{\infty} \frac{1}{3^i} \phi\left(\frac{x}{3^{i+1}}, \frac{y}{3^{i+1}}, \frac{z}{3^{i+1}}\right) < \infty.$$
Then there exists a unique multiplicative inverse mapping $A : X \rightarrow Y$ which satisfies (1.1) and

$$|f(x) - A(x)| \leq \Phi(x, x, x)$$

for all $x \in X$.

**Proof.** Replacing $(x, y, z)$ by $(\xi, \xi, \xi)$ in (2.1), we obtain

$$\left| \frac{1}{3} f \left( \frac{x}{3} \right) - f(x) \right| \leq \phi \left( \frac{x}{3}, \frac{x}{3}, \frac{x}{3} \right).$$

(2.2)

Again replacing $x$ by $\xi$ in (2.2) and dividing by 3 we get

$$\left| \frac{1}{3^2} f \left( \frac{x}{3^2} \right) - f(x) \right| \leq \phi \left( \frac{x}{3^2}, \frac{x}{3^2}, \frac{x}{3^2} \right) + \frac{1}{3} \phi \left( \frac{x}{3^2}, \frac{x}{3^2}, \frac{x}{3^2} \right).$$

Again replacing $x$ by $\xi$ in the above inequality and dividing by 3 we get

$$\left| \frac{1}{3^n} f \left( \frac{x}{3^n} \right) - f(x) \right| \leq \sum_{i=0}^{2} \frac{1}{3^i} \phi \left( \frac{x}{3^i}, \frac{x}{3^i}, \frac{x}{3^i} \right).$$

Proceeding further and using induction on a positive integer $n$, we get

$$\left| \frac{1}{3^n} f \left( \frac{x}{3^n} \right) - f(x) \right| \leq \sum_{i=0}^{\infty} \frac{1}{3^i} \phi \left( \frac{x}{3^i+1}, \frac{x}{3^i+1}, \frac{x}{3^i+1} \right).$$

(2.3)

for all $x \in X$. In order to prove the convergence of the sequence $\left\{ \frac{1}{3^n} f \left( \frac{x}{3^n} \right) \right\}$, replace $x$ by $\xi$ in (2.3) and divide by $3^p$, we find that for $n > p > 0$

$$\left| \frac{1}{3^p} f \left( \frac{x}{3^p} \right) - \frac{1}{3^{n+p}} f \left( \frac{x}{3^{n+p}} \right) \right| = \frac{1}{3^p} \left| f \left( \frac{x}{3^p} \right) - f \left( \frac{x}{3^{n+p}} \right) \right|$$

$$\leq \sum_{i=0}^{\infty} \frac{1}{3^{p+i}} \phi \left( \frac{x}{3^{p+i+1}}, \frac{x}{3^{p+i+1}}, \frac{x}{3^{p+i+1}} \right)$$

$$\leq \sum_{i=p}^{\infty} \frac{1}{3^{i}} \phi \left( \frac{x}{3^{i+1}}, \frac{x}{3^{i+1}}, \frac{x}{3^{i+1}} \right).$$

Allow $p \rightarrow \infty$, the right-hand side of the above inequality tends to 0. Thus the sequence $\left\{ \frac{1}{3^n} f \left( \frac{x}{3^n} \right) \right\}$ is a Cauchy sequence. Thus we may
define a mapping \( A : X \to Y \) by

\[
A(x) := \lim_{n \to \infty} \frac{1}{3^n} f \left( \frac{x}{3^n} \right)
\]

for all \( x \in X \). By (2.3) with \( n \to \infty \), we have

\[
|f(x) - A(x)| \leq \Phi(x, x, x)
\]

for all \( x \in X \). Replacing \((x, y, z)\) by \((\frac{x}{3^n}, \frac{y}{3^n}, \frac{z}{3^n})\) in (2.1) and dividing by \(3^n\) we obtain

\[
\begin{align*}
1 & \left| 3^n f \left( \frac{1}{3^n} \left( \frac{x+y+z}{3} \right) \right) - f \left( \frac{1}{3^n} (x+y+z) \right) \right| \\
& \quad - \frac{2f(\frac{u}{3^n})f(\frac{v}{3^n})f(\frac{w}{3^n})}{f(\frac{u}{3^n})f(\frac{v}{3^n})f(\frac{w}{3^n}) + f(\frac{u}{3^n})f(\frac{w}{3^n}) + f(\frac{v}{3^n})f(\frac{u}{3^n})} \\
& \leq \left| 3^n \phi \left( \frac{x}{3^n}, \frac{y}{3^n}, \frac{z}{3^n} \right) \right|
\end{align*}
\]

for all \((x, y, z)\) \( \in X^3 \), where \( u = \frac{x+y}{2}, v = \frac{y+z}{2} \) and \( w = \frac{z+x}{2} \). Letting \( n \to \infty \), we have

\[
A \left( \frac{x+y+z}{3} \right) - A(x+y+z) = \frac{2A(u)A(v)A(w)}{A(u)A(v) + A(v)A(w) + A(w)A(u)}
\]

for all \((x, y, z)\) \( \in X^3 \), where \( u = \frac{x+y}{2}, v = \frac{y+z}{2} \) and \( w = \frac{z+x}{2} \). Now let \( B : X \to Y \) be another function which satisfies the equation (1.1) and \( |f(x) - B(x)| \leq \Phi(x, x, x) \) for all \( x \in X \). Since \( 3^n B(x) = B(\frac{x}{3^n}) \) and \( 3^n A(x) = A(\frac{x}{3^n}) \), we have

\[
|B(x) - A(x)| = \frac{1}{3^n} \left| B \left( \frac{x}{3^n} \right) - A \left( \frac{x}{3^n} \right) \right| \\
\leq \frac{1}{3^n} \left( \left| B \left( \frac{x}{3^n} \right) - f \left( \frac{x}{3^n} \right) \right| + \left| f \left( \frac{x}{3^n} \right) - A \left( \frac{x}{3^n} \right) \right| \right) \\
\leq 2 \sum_{i=0}^{\infty} \frac{1}{3^{n+i+1}} \phi \left( \frac{x}{3^{n+i+1}}, \frac{x}{3^{n+i+1}}, \frac{x}{3^{n+i+1}} \right)
\]

for all \( x \in X \). Allowing \( n \to \infty \) in the above inequality, we find that \( A \) is unique. This completes the proof of the theorem.

**Corollary 2.** Let \( X \) and \( Y \) be spaces of non-zero real numbers. Assume that \( f : X \to Y \) satisfies the functional inequality

\[
|D_f(x, y, z)| \leq \delta
\]
for all $x, y, z \in X$. Then there exists a unique multiplicative inverse mapping $A : X \to Y$ which satisfies (1.1) and

$$|f(x) - A(x)| \leq 3\delta$$

for all $x \in X$.

Proof. Let $\phi(x, y, z) = \delta$ for all $x, y, z \in X$. Then by Theorem 1,

$$\Phi(x) = \sum_{i=0}^{\infty} \frac{\delta}{3^i} = 3$$

for all $x \in X$. This completes the proof of the corollary.

\[ \square \]

**Theorem 3.** Let $X$ and $Y$ be spaces of non-zero real numbers. Assume that $f : X \to Y$ satisfies the functional inequality

(2.4)  

$$|D_f(x, y, z)| \leq \psi(x, y, z)$$

for all $x, y, z \in X$, where $\psi : X^3 \to Y$ is a function such that for all $x, y, z \in X$

$$\Psi(x, y, z) := \sum_{i=0}^{\infty} 3^{i+1} \psi(3^i x, 3^i y, 3^i z) < \infty.$$  

Then there exists a unique multiplicative inverse mapping $A : X \to Y$ which satisfies (1.1) and

$$|f(x) - A(x)| \leq \Psi(x, x, x)$$

for all $x \in X$.

Proof. Replacing $(x, y, z)$ by $(x, x, x)$ in (2.4) and multiplying by 3, we obtain

(2.5)  

$$|f(x) - 3f(3x)| \leq 3\psi(x, x, x).$$

Again replacing $x$ by $3x$ in (2.5) and multiplying by 3 we get

$$|f(x) - 3^2 f(3^2 x)| \leq 3\psi(x, x, x) + 3^2 \phi(3x, 3x, 3x).$$

Again replacing $x$ by $3x$ in the above inequality and multiplying by 3 we get

$$|f(x) - 3^3 f(3^3 x)| \leq \sum_{i=0}^{\infty} 3^{i+1} \psi(3^i x, 3^i x, 3^i x).$$
Proceeding further and using induction on a positive integer \( n \), we get

\[
|f(x) - 3^n f(3^n x)| \leq \sum_{i=0}^{n-1} 3^{i+1} \psi (3^i x, 3^i x, 3^i x)
\]

(2.6)

\[
\leq \sum_{i=0}^{\infty} 3^{i+1} \psi (3^i x, 3^i x, 3^i x)
\]

for all \( x \in X \). In order to prove the convergence of the sequence \( \{3^n f(3^n x)\} \), replace \( x \) by \( 3^p x \) in (2.6) and divide by \( 3^p \), we find that for \( n > p > 0 \)

\[
|3^p f(3^p x) - 3^n f(3^n x)| = 3^p |f(3^p x) - 3^n f(3^n x)|
\]

\[
\leq \sum_{i=0}^{\infty} 3^{p+i+1} \phi (3^{p+i} x, 3^{p+i} x, 3^{p+i} x)
\]

\[
\leq \sum_{i=p}^{\infty} 3^{i+1} \phi (3^i x, 3^i x, 3^i x).
\]

Allow \( p \to \infty \), the right-hand side of the above inequality tends to 0. Thus the sequence \( \{3^n f(3^n x)\} \) is a Cauchy sequence. Thus we may define a mapping \( A : X \to Y \) by

\[
A(x) := \lim_{n \to \infty} 3^n f(3^n x)
\]

for all \( x \in X \). By (2.6) with \( n \to \infty \), we have

\[
|f(x) - A(x)| \leq \Psi(x, x, x)
\]

for all \( x \in X \). Replacing \((x, y, z)\) by \((3^n x, 3^n y, 3^n z)\) in (2.4) and multiplying by \( 3^n \) we obtain

\[
3^n \left| f \left( 3^n \left( \frac{x+y+z}{3} \right) \right) - f \left( 3^n (x+y+z) \right) \right|
\]

\[
- \frac{2 f(3^n x) f(3^n y) f(3^n z)}{f(3^n x) f(3^n y) + f(3^n y) f(3^n z) + f(3^n z) f(3^n x)}
\]

\[
\leq \frac{1}{3} 3^{n+1} \psi(3^n x, 3^n y, 3^n z)
\]

for all \((x, y, z) \in X^3 \). Since \( \Psi(x, y, z) \) converses, letting \( n \to \infty \), we have

\[
A \left( \frac{x+y+z}{3} \right) - A(x+y+z) = \frac{2 A(x) A(y) A(z)}{A(x) A(y) + A(y) A(z) + A(z) A(x)}
\]
for all \((x, y, z) \in X^3\). Now let \(B : X \to Y\) be another function which satisfies the equation \((1.1)\) and \(|f(x) - B(x)| \leq \Psi(x, x, x)\) for all \(x \in X\). Since \(B(3^n x) = \frac{1}{3^n} B(x)\) and \(A(3^n x) = \frac{1}{3^n} A(x)\) we have

\[
|B(x) - A(x)| = 3^n |B(3^n x) - A(3^n x)|
\leq 3^n (|B(3^n x) - f(3^n x)| + |f(3^n x) - A(3^n x)|)
\leq 2 \sum_{i=0}^{\infty} 3^{n+i+1} \Psi(3^{n+i} x, 3^{n+i} x, 3^{n+i} x)
\]

for all \(x \in X\). Allowing \(n \to \infty\) in the above inequality, we find that \(A\) is unique. This completes the proof of the theorem.

\(\square\)

**Theorem 4.** Let \(X\) and \(Y\) be spaces of non-zero real numbers. Assume that \(f : X \to Y\) satisfies the functional inequality

\[
|E f(x, y, z)| \leq \phi(x, y, z)
\]

(2.7)

for all \(x, y, z \in X\), where \(\phi : X^3 \to Y\) is a function such that for all \(x, y, z \in X\)

\[
\Phi(x, y, z) := \sum_{i=0}^{\infty} \frac{1}{3^i} \phi \left( \frac{x}{3^{i+1}}, \frac{y}{3^{i+1}}, \frac{z}{3^{i+1}} \right) < \infty.
\]

Then there exists a unique multiplicative inverse mapping \(A : X \to Y\) which satisfies \((1.2)\) and

\[
|f(x) - A(x)| \leq \Phi(x, x, x)
\]

for all \(x \in X\).

**Proof.** Replacing \((x, y, z)\) by \(\left( \frac{x}{3}, \frac{y}{3}, \frac{z}{3} \right)\) in \((2.7)\), we obtain

\[
\left| \frac{1}{3} f \left( \frac{x}{3} \right) - f(x) \right| \leq \phi \left( \frac{x}{3}, \frac{x}{3}, \frac{x}{3} \right).
\]

By the same method of proof in Theorem 1, we complete the proof. \(\square\)

**Corollary 5.** Let \(X\) and \(Y\) be spaces of non-zero real numbers. Assume that \(f : X \to Y\) satisfies the functional inequality

\[
|E f(x, y, z)| \leq \delta
\]

for all \(x, y, z \in X\). Then there exists a unique multiplicative inverse mapping \(A : X \to Y\) which satisfies \((1.2)\) and the inequality

\[
|f(x) - A(x)| \leq 3\delta
\]

for all \(x \in X\).
for all $x \in X$.

**Theorem 6.** Let $X$ and $Y$ be spaces of non-zero real numbers. Assume that $f : X \rightarrow Y$ satisfies the functional inequality

\begin{equation}
|E_f(x, y, z)| \leq \psi(x, y, z)
\end{equation}

for all $x, y, z \in X$, where $\psi : X^3 \rightarrow Y$ is a function such that for all $x, y, z \in X$

$$
\Psi(x, y, z) := \sum_{i=0}^{\infty} 3^{i+1} \psi(3^i x, 3^i y, 3^i z) < \infty.
$$

Then there exists a unique multiplicative inverse mapping $A : X \rightarrow Y$ which satisfies (1.2) and the inequality

$$
|f(x) - A(x)| \leq \Psi(x, x, x)
$$

for all $x \in X$.

**Proof.** Replacing $(x, y, z)$ by $(x, x, x)$ in (2.8) and multiplying by 3, we obtain

$$
|f(x) - 3f(3x)| \leq 3\psi(x, x, x).
$$

By the same method of proof in Theorem 3, we complete the proof. \(\square\)
