Likelihood Based Confidence Intervals for the Common Scale Parameter in the Inverse Gaussian Distributions

Woo Dong Lee1) · Kil Ho Cho2) · Young Joon Cha3) · Jung Hwan Ko4)

Abstract

This paper focuses on the likelihood based confidence intervals for two inverse gaussian distributions when the parameter of interest is common scale parameter. Confidence intervals based on signed loglikelihood ratio statistic and modified signed loglikelihood ratio statistics will be compared in small sample through an illustrative simulation study.

Keywords: Confidence intervals, Modified signed log likelihood ratio, Signed log likelihood ratio

1. Introduction

The inverse gaussian distribution has potentially useful applications in a wide variety of fields such as biology, economics, reliability theory, life testing and social science as discussed in Chhikara and Folks (1978,1989) and Seshdri (1999). Tweed (1957a, 1957b) studied many important statistical properties of the inverse gaussian distribution and discussed the similarity between statistical methods based on the inverse gaussian distribution and those based on the normal theory.

The scale parameter of the inverse gaussian distribution plays important role in the analysis of reciprocals (Tweed, 1957a; Fries and Bathacharyya, 1983) and regression models (Whitmore 1979).

In this paper, our purpose is to make statistical inference on the common scale parameter of two independent inverse Gaussian distributions. Specially, we want to construct an approximate confidence interval for common scale parameter based on likelihood-based methods. We propose two likelihood-based methods which are the signed loglikelihood ratio statistic and the modified signed loglikelihood ratio statistic (Barndorff-Nielsen and Cox 1994). It is well known that the modified signed loglikelihood ratio statistic is highly accurate even in small sample.

This article is organized as follows. In Section 2, we introduce the likelihood-based inference methods, that is, the signed loglikelihood ratio statistic and the modified signed loglikelihood ratio statistic which will employ to construct confidence intervals for the common scale parameter. In Section 3, we derive the statistics given in Section 2 in details. In Section 4, through an illustrative simulation study, the performance of the confidence interval from two statistics will be compared with respect to estimated coverage probabilities and expected lengths when the sample size is small.

2. Likelihood-based Methods

Let $X$ be an inverse Gaussian distribution with parameters $\lambda$ and $\mu_1$, and its probability density function is given by

$$f(x | \mu_1, \lambda) = \sqrt{\frac{\lambda}{2\pi}} x^{-\frac{3}{2}} \exp\left\{-\frac{\lambda(x-\mu_1)^2}{2\mu_1^2} x\right\}, x>0, \lambda>0, \mu_1>0,$$

and let $Y$ be also an inverse Gaussian distribution with parameters $\lambda$ and $\mu_2$, and its probability density function is given by

$$g(y | \mu_2, \lambda) = \sqrt{\frac{\lambda}{2\pi}} y^{-\frac{3}{2}} \exp\left\{-\frac{\lambda(y-\mu_2)^2}{2\mu_2^2} y\right\}, x>0, \lambda>0, \mu_2>0,$$

and assume $X$ and $Y$ are independently distributed.

Let $X_1, X_2, \ldots, X_n$ be a random sample from $X$ and $Y_1, Y_2, \ldots, Y_m$ be a random sample from $Y$.

Then the likelihood function of $\lambda, \mu_1$ and $\mu_2$ is given by

$$L(\lambda, \mu_1, \mu_2) = \left(\frac{\lambda}{2\pi}\right)^{\frac{n+m}{2}} \left(\prod_{i=1}^{n} x_i^{-3/2}\right) \left(\prod_{j=1}^{m} y_j^{-3/2}\right) \times \exp\left\{-\frac{\lambda}{2\mu_1^2} \sum_{i=1}^{n} \frac{(x_i-\mu_1)^2}{x_i} - \frac{\lambda}{2\mu_2^2} \sum_{j=1}^{m} \frac{(y_j-\mu_2)^2}{y_j}\right\}.$$
Likelihood Based Confidence Intervals for the Common Scale Parameter in the Inverse Gaussian Distributions

Let \( \Theta=(\lambda, \mu_1, \mu_2)=(\lambda, \omega) \), where \( \omega=(\mu_1, \mu_2) \). Here \( \lambda \) is the scalar parameter of interest and \( \omega \) is a nuisance parameter vector. Then the loglikelihood function of \( \Theta \) is given by

\[
\ell(\Theta) \propto n+2 \log(\lambda) - \frac{3}{2} \left( \sum_{i=1}^{n} \log(x_i) + \sum_{j=1}^{m} \log(y_j) \right) - \frac{\lambda}{2\mu_1^2} \sum_{i=1}^{n} \frac{(x_i-\mu_1)^2}{x_i} - \frac{\lambda}{2\mu_2^2} \sum_{j=1}^{m} \frac{(y_j-\mu_2)^2}{y_j}
\]

The above loglikelihood function can be re-expressed as

\[
\ell(\Theta) \propto n+2 \log(\lambda) - \frac{3}{2} \left( \sum_{i=1}^{n} \log(x_i) + \sum_{j=1}^{m} \log(y_j) \right) + \lambda \left( \frac{n}{\mu_1} + \frac{m}{\mu_2} \right) - \frac{\lambda}{2\mu_1^2} \sum_{i=1}^{n} x_i - \frac{\lambda}{2\mu_2^2} \sum_{j=1}^{m} y_j
\]

From this loglikelihood, the maximum likelihood estimates of \( \Theta \) are given by

\[
\hat{\mu}_1 = \frac{\sum_{i=1}^{n} x_i}{n}, \quad \hat{\mu}_2 = \frac{\sum_{j=1}^{m} y_j}{m} \quad \text{and} \quad \hat{\lambda} = \frac{n+2}{\sum_{i=1}^{n} (x_i)^{-1} + \sum_{j=1}^{m} (y_j)^{-1}}.
\]

For fixed \( \lambda \), the constrained maximum likelihood estimates of \( \omega \) are

\[
\tilde{\omega}_1(\lambda)=\tilde{x} \quad \text{and} \quad \tilde{\omega}_2(\lambda)=\tilde{y}.
\]

Denote it as \( \tilde{\omega}(\lambda)=(\tilde{\omega}_1(\lambda), \tilde{\omega}_2(\lambda)) \).

One can make statistical inference about \( \lambda \) based on the signed loglikelihood ratio statistics given by

\[
r=r(\lambda)=sgn(\hat{\lambda}-\lambda) \left( \ell(\hat{\lambda}, \tilde{\omega}) - \ell(\lambda, \tilde{\omega}(\lambda)) \right)^{1/2}.
\]

It is well known that this statistic \( r \) distributed as standard normal distribution with asymptotic error \( O(n^{-1/2}) \). That is \( r \) is the first-order approximation. For testing \( H_0: \lambda=\lambda_0 \), a two sided \( p \)-value can be obtained from

\[
\text{\( p \)-value}=2P\{r>r_0 \mid \} \approx 2\{1 - \Phi( \mid r_0 \mid ) \},
\]

where \( \Phi(\cdot) \) is the distribution function of standard normal distribution and \( r_0=r(\lambda_0) \) is the observed values of \( r \) under the null hypothesis. Furthermore, the approximate \( 100(1-\alpha)% \) confidence interval for \( \lambda \) can be obtained from
\[
\{ \lambda : | r(\lambda) | \leq z_{\alpha/2} \},
\]
where \( z_{\alpha/2} \) is the 100(1- \( \alpha/2 \))th percentile of the standard normal distribution.

Generally, the first-order approximation is not accurate especially when the sample size is small. There are several ways to improve the accuracy of the approximation by adjusting the signed loglikelihood ratio statistics \( r \).

Among the others, the modified signed loglikelihood ratio statistic, \( r^* \), developed by Barndorff-Nielsen (1986, 1991), is quite accurate approximation. In fact, this is the third-order approximation and is given by

\[
r^* = r^*(\lambda) = r(\lambda) + r(\lambda)^{-1} \log \left\{ \frac{u(\lambda)}{r(\lambda)} \right\},
\]

where \( u(\lambda) \) is a statistic given by

\[
u(\lambda) = \frac{| l_{\theta}(\widehat{\lambda}, \widehat{\omega}) - l_{\theta}(\lambda, \widehat{\omega}(\lambda)) |}{\sqrt{\{ j_{\theta\theta}(\lambda) | j_{\omega\omega}(\lambda) \}^{1/2}}},
\]

where the sample-space derivatives are defined by

\[
il_{\theta}(\lambda, \omega) = \frac{\partial}{\partial \theta} l(\lambda, \omega; \theta),
\]

the mixed derivatives as

\[
il_{\omega\theta}(\lambda, \omega) = \frac{\partial}{\partial \omega} l_{\theta}(\lambda, \omega),
\]

and \( j_{\theta\theta}(\lambda, \omega) \) is the observed information matrix and \( j_{\omega\omega}(\lambda, \widehat{\omega}(\lambda)) \) is the observed nuisance information matrix (Barndorff-Nielsen, 1991). This statistic \( r^* \) also distributed as standard normal distribution with asymptotic error \( O(n^{-3/2}) \). One can also obtain the \( p \)-value of two sided test for testing \( H_0: \lambda = \lambda_0 \) based on \( r^* \) as

\[
p\text{-value} = 2P\{ r^* > | r^*_0 | \} = 2\{ 1 - \Phi( | r^*_0 | ) \},
\]

which will be more accurate than (2). And the approximate 100(1- \( \alpha \))% confidence interval can be obtained from

\[
\{ \lambda : | r^*(\lambda) | \leq z_{\alpha/2} \}.
\]
3. Derivation of the Signed Log Likelihood Ratio Statistic and the Modified Signed Log Likelihood Ratio Statistic

Now, the signed log likelihood ratio statistic given in (1) can be easily obtained from the log likelihood function. But the modified signed log likelihood ratio is rather difficult.

Since the two sample inverse gaussian model is a full rank exponential model, the log likelihood function based on the sample data is only related to a minimum sufficient statistic

\[ t = (t_1, t_2, t_3), \]

where

\[ t_1 = \sum_{i=1}^{n} x_i^{-1} + \sum_{j=1}^{m} y_j^{-1}, \quad t_2 = \sum_{i=1}^{n} x_i \quad \text{and} \quad t_3 = \sum_{u=1}^{m} y_u. \]

The loglikelihood function can be rewritten as

\[
\begin{align*}
\log l(\lambda, \omega; t) &\propto \frac{n+m}{2} \log(\lambda) - \frac{3}{2}(\sum_{i=1}^{n} \log(x_i) + \sum_{j=1}^{m} \log(y_j)) + \lambda \left( \frac{n}{\mu_1} + \frac{m}{\mu_2} \right) - \frac{\lambda}{2} t_1 \\
&\quad - \frac{\lambda}{2\mu_1^2} t_2 - \frac{\lambda}{2\mu_2^2} t_3.
\end{align*}
\]

There is one-to-one transformation between the maximum likelihood estimator \( \hat{\theta} = (\lambda, \mu_1, \mu_2) \) and \( t = (t_1, t_2, t_3) \), and the transformation Jacobian matrix is \( \partial \hat{\theta}/\partial t \).

Hence the sample space derivatives with respect to \( \hat{\theta} \) in the formula (5) for \( u \) can be derived based on the sample space derivatives with respect to \( t \). And using the identity \( j_{\theta\theta}(\hat{\theta}) = j_{\theta\theta}(\hat{\theta}) \) (Barndorff-Nielsen and Cox, 1994) and by canceling the determinant of the transformation Jacobian matrix, one can show that \( u \) reduces to the following form:

\[
u(\lambda) = \left| \frac{I_{\lambda} (\lambda, \omega) - I_{\lambda}(\lambda, \omega(\lambda))}{I_{\theta t}(\lambda, \omega)} \right| \left( \frac{\left| j_{\theta\theta}(\lambda, \omega) \right|}{\left| j_{\omega}(\lambda, \omega(\lambda)) \right|} \right)^{1/2},\]

where the sample space derivatives \( I_{\lambda} (\theta) = \partial^2 \log l(\theta; t)/\partial \theta \partial t \) and the mixed derivatives \( I_{\omega}(\theta) = \partial^2 \log l(\theta; t)/\partial \omega \partial t \) are given by

\[
I_{\lambda} (\lambda, \omega) = \frac{n+m}{2} \log(\lambda) - \frac{3}{2}(\sum_{i=1}^{n} \log(x_i) + \sum_{j=1}^{m} \log(y_j)) + \lambda \left( \frac{n}{\mu_1} + \frac{m}{\mu_2} \right) - \frac{\lambda}{2} t_1 \\
- \frac{\lambda}{2\mu_1^2} t_2 - \frac{\lambda}{2\mu_2^2} t_3.
\]
\[ l_\theta(\theta) = \left( \frac{-\lambda}{2}, \frac{-\lambda}{2\mu_1}, -\frac{\lambda}{2\mu_2} \right)^T \quad \text{and} \quad l_\omega(\theta) = \begin{pmatrix} 0 & \frac{\lambda}{\mu_1} \\ 0 & 0 \end{pmatrix} \]

respectively. The observed information matrix \( j_{\theta\theta}(\lambda, \omega) \) is given by

\[
j_{\theta\theta}(\lambda, \omega) = \begin{pmatrix} \frac{n + m}{\lambda^2} & \frac{n}{\mu_1} & \frac{m}{\mu_2} \\ \frac{n}{\mu_1} & \frac{3\lambda t_2}{\mu_1} & 3(\lambda t_2 - 2n\lambda) \\ \frac{m}{\mu_2} & \frac{3\lambda t_2}{\mu_2} & \frac{3\lambda t_2}{\mu_2} \\ 0 & 0 & 0 \end{pmatrix}.
\]

And the mixed derivative matrix \( l_{\theta\theta}(\theta) \) is given by

\[
l_{\theta\theta}(\theta) = \begin{pmatrix} -\frac{1}{2} & 0 & 0 \\ -\frac{1}{2} \mu_1^2 & \frac{\lambda}{\mu_1^3} & 0 \\ -\frac{1}{2} \mu_2^2 & 0 & \frac{\lambda}{\mu_2^3} \end{pmatrix}.
\]

Finally, the observed nuisance information matrix \( j_{\omega\omega}(\lambda, \omega(\lambda)) \) is given by

\[
j_{\omega\omega}(\lambda, \omega(\lambda)) = \begin{pmatrix} \frac{3\lambda_2}{\mu_1^2} - \frac{2n\lambda}{\mu_1^3} & 0 \\ 0 & \frac{3\lambda_3}{\mu_2^2} - \frac{2n\lambda}{\mu_2^3} \end{pmatrix}.
\]

Therefore, the statistic \( t(\lambda) \) can be calculated using the above equations. Hence \( r(\lambda) \) can be obtained from \( r(\lambda) \) and \( t(\lambda) \). Now, we are ready to obtain confidence intervals for \( \lambda \) using (3) and (9).

### 4. An Illustrative Simulation Study

In this section, we will give an example and some simulation results. The aim of our simulation is to compare the estimated coverage probability, coverage error, upper and lower error probability, and average lengths for \( r \) and \( r' \). The coverage error is defined as the absolute difference between the estimated
Likelihood Based Confidence Intervals for the Common Scale Parameter in the Inverse Gaussian Distributions

coverage probability and nominal value (0.90). And upper and lower error probability is the percentage of the intervals falling above and below the true parameter.

Example. The following two groups of data are artificially generated from two independent inverse gaussian distribution with parameters IG(5, 2) and IG(0.5, 2), respectively. The data are as follows:

<table>
<thead>
<tr>
<th>X</th>
<th>2.610</th>
<th>3.302</th>
<th>1.121</th>
<th>12.769</th>
<th>0.706</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y</td>
<td>0.164</td>
<td>0.572</td>
<td>0.201</td>
<td>0.896</td>
<td>0.390</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>0.562</td>
<td>0.285</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>0.668</td>
<td></td>
</tr>
</tbody>
</table>

From the above data, the maximum likelihood estimates of $\theta$ were $\hat{\mu}_1 = 4.102$, $\hat{\mu}_2 = 0.467$, $\hat{\lambda} = 1.6178$. The 95% confidence interval for $\lambda$ based on $r$ was (0.672, 3.199) and $r^*$ was (0.482, 2.745). The length of the 95% confidence interval based on $r$ and $r^*$ were 2.528 and 2.263, respectively. The two intervals contain the true parameter and the length of the interval based on $r^*$ is shorter than that based on $r$.

We perform simulation to estimate the coverage probability, coverage error, upper and lower error probability and average length. We assume that sample sizes are $(n, m) = (5, 5), (10, 5), (5, 10), (10, 10), (10, 15)$ and $(15, 15)$. And $(\lambda, \mu_1, \mu_2) = (3, 4, 3), (0.5, 4, 3)$ and $(1, 4, 3)$. We have generated 10,000 independent random samples. The simulation results are given from Table 1 to Table 3.

From tables, we observe that the coverage probabilities are lower than the nominal level 0.90, or equivalently, the coverage errors are relatively large for the interval based on the siged log likelihood statistic $r$. Moreover, the biases of the upper error probabilities of $r$ are large and they extremely asymmetric in small sample size.

In contrast, the confidence interval based on $r^*$ gives nearly the exact coverage probabilities. Furthermore, its upper and lower error probabilities are close to the nominal error levels and they are much more symmetric than those of the interval based on $r$.

The average length of the interval based on $r^*$ is shorter than that of the interval based on $r$.

Overall, based on the comparison criteria examined in the above, the confidence interval based on $r^*$ performs much better than the confidence interval based on $r$.

We have tried several parameter values different from Table 1 to Table 3, but their results were almost same.
