(Received November 29, 2013 : Accepted November 30, 2013)

Abstract: At Pt(111), Pt(100), Pt, and Rh interfaces, the Frumkin adsorption isotherm of under-potentially deposited hydrogen (UPD H) and related electrode kinetic data are determined using the standard Gibbs energy of adsorption. The Temkin adsorption isotherm of UPD H correlating with the Frumkin adsorption isotherm of UPD H is readily determined using the correlation constants between the Temkin and Frumkin or Langmuir adsorption isotherms. At the Pt(111), Pt(100), Pt, and Rh interfaces, the lateral repulsive interaction between the UPD H species is interpreted using the interaction parameter for the Frumkin adsorption isotherm. The lateral repulsive interaction between the UPD H species at the Pt(111), Pt(100), Pt, and Rh interfaces is significantly different from the lateral attractive interaction between the overpotentially deposited hydrogen (OPD H) species at Pt, Ir, and Pt-Ir alloy interfaces.

Key words: Underpotentially and overpotentially deposited hydrogen; Frumkin, Langmuir, and Temkin adsorption isotherms; Pt group metal electrodes; Standard Gibbs energy of adsorption; Correlation constants

1. Introduction

It is well known that underpotentially deposited hydrogen (UPD H) and overpotentially deposited hydrogen (OPD H) occupy different surface adsorption sites and act as two distinguishable electroadsorbed H species, and that only OPD H can contribute to the cathodic H₂ evolution reaction (HER).1-5 Although the Frumkin and Langmuir adsorption isotherms may be regarded as classical models and theories, it is preferable to consider the Frumkin and Langmuir adsorption isotherms for UPD H and OPD H rather than equations of the electrode kinetics and thermodynamics for UPD H and OPD H because these adsorption isotherms are associated more directly with the atomic mechanisms of UPD H and OPD H.6 However, there is not much reliable information on the Frumkin and Temkin adsorption isotherms of UPD H and OPD H and related electrode kinetic data, i.e., the fractional surface coverage vs. potential (θ vs. E), interaction parameter (g), and equilibrium constant (K). A quantitative relationship between the Temkin and Frumkin or Langmuir adsorption isotherms of UPD H and OPD H has not been developed to study the cathodic HER. Note that the Frumkin adsorption isotherms of UPD H and OPD H and related electrode kinetic data (θ vs. E, g, K) have never been experimentally determined using conventional methods.2,3 Therefore, the thermodynamic data for UPD H, i.e., the standard Gibbs energy of adsorption (ΔG°θ) and rate of change (r) of ΔG°θ with θ(0 ≤ θ ≤ 1), have been frequently investigated and reported.1-5
To determine the Frumkin, Langmuir, and Temkin adsorption isotherms of UPD H and OPD H, the phase-shift method and correlation constants have been originally developed on the basis of relevant experimental results and data.\textsuperscript{7} The theoretical and experimental backgrounds and basic procedure of the phase-shift method for determining the Frumkin, Langmuir, and Temkin adsorption isotherms are described elsewhere.\textsuperscript{8}

In this paper, we determined the electrode kinetic data (g, K) for the Frumkin adsorption isotherms (θ vs. E) of UPD H at Pt(111), Pt(100), Pt, and Rh/aqueous solution interfaces using ΔG\textsubscript{θ}\textsuperscript{o} with θ\textsuperscript{2-3}.\textsuperscript{4} The Temkin adsorption isotherms of UPD H correlating with the Frumkin adsorption isotherms of UPD H were readily determined using the correlation constants.\textsuperscript{7,8} The Frumkin and Temkin adsorption isotherms of UPD H and electrode kinetic data (θ vs. E, g, K) have never been determined using ΔG\textsubscript{θ}\textsuperscript{o} with θ(0 ≤ θ ≤ 1) and the correlation constants.

2. Determination of the Frumkin adsorption isotherm using the standard Gibbs energy of adsorption

Under the Frumkin adsorption conditions, the relationship between the equilibrium constant (K) and the standard Gibbs energy of adsorption (ΔG\textsubscript{θ}\textsuperscript{o}) is\textsuperscript{9}

\[
2.3RT \log K = -ΔG_0^θ \tag{1}
\]

\[K = K_o \exp(-gθ) \tag{2}\]

\[g = \frac{rRT}{C^+} \tag{3}\]

where R is the gas constant, T is the absolute temperature, K is the equilibrium constant for the Frumkin adsorption isotherm, ΔG\textsubscript{θ}\textsuperscript{o} is the standard Gibbs energy of adsorption with θ(0 ≤ θ ≤ 1), K\textsubscript{o} is the equilibrium constant for the Frumkin adsorption isotherm at g = 0, g is the interaction parameter for the Frumkin adsorption isotherm, θ(0 ≤ θ ≤ 1) is the fractional surface coverage, and r is the rate of change of ΔG\textsubscript{θ}\textsuperscript{o} with θ(0 ≤ θ ≤ 1). The dimension of K is described elsewhere.\textsuperscript{10} The electrode kinetic and thermodynamic data (g, r, ΔG\textsubscript{θ}\textsuperscript{o}) for the Frumkin adsorption isotherms of UPD H at the Pt(111), Pt(100), Pt, and Rh interfaces are summarized in Table 1.\textsuperscript{2-5}

The Frumkin adsorption isotherm assumes that the lateral interaction effect is not negligible. It is well known that the Langmuir adsorption isotherm is a special case of the Frumkin adsorption isotherm. Note that when g = 0 in Eqs. 2 and 3, the Langmuir adsorption isotherm is obtained. For the Langmuir adsorption isotherm, the lateral interaction effect is assumed to be negligible. The Frumkin adsorption isotherm (θ vs. E) can be expressed as follows\textsuperscript{9}

\[\left[\frac{θ}{1-θ}\right] \exp(gθ) = K_o C^+ \exp(-EF/RT) \tag{4}\]

where C\textsuperscript{+} is the concentration of ions (i.e., H\textsuperscript{+}) in the bulk solution, E is the negative potential, and F is Faraday’s constant.

The electrode kinetic data (g, K\textsubscript{o}, K) for the Frumkin adsorption isotherms of UPD H shown in Table 2 are calculated using Eqs. 1 to 4 and the relevant experimental data shown in Table 1. In Table 2, we assume that the adsorptions of UPD H shown in Table 1 depend on θ(0 ≤ θ ≤ 1) and E regardless of the temperature ranges. The ranges of θ given in Table 1 (see Footnotes b to d) do not influence the

\(^a\) Calculated using Eq. 3 and the relevant experimental data shown in Table 1. \(^b\) Calculated using Eqs. 1 to 4 and the relevant experimental data shown in Table 1. \(^A\) A is the equilibrium constant at \( g=0 \), i.e., \( K_o \). Note that the values of \( g \) and \( K_o \) for the Temkin adsorption isotherms are approximately 4.6 and 10 times greater than those for the correlated Frumkin adsorption isotherms, respectively. The Temkin adsorption isotherms are valid and effective only at \( 0.2 < \theta < 0.8 \).

3. Determination of the Temkin adsorption isotherm using the correlation constants

At intermediate values of \( \theta \), i.e., \( 0.2 < \theta < 0.8 \), the pre-exponential term, \([\theta(1-\theta)]\), in Eq. 4 varies little with \( \theta \) in comparison with the variation of the exponential term, \( \exp(g\theta) \). Under these approximate conditions, the Temkin adsorption isotherm can be simply derived from the Frumkin adsorption isotherm. The Temkin adsorption isotherm (\( \theta \) vs. \( E \)) can be expressed as follows\(^b\)

\[
\exp(g\theta) = K_o C^* \exp(-EF/RT) \tag{5}
\]

The physical meaning of \( g \) for the Temkin adsorption isotherm (Eq. 5) is clearly different from that for the Frumkin adsorption isotherm (Eq. 4). Note that \( g \) in Eq. 5 is practically determined by the slope of experimental data for \( 0.2 < \theta < 0.8 \) (see Figs. 1 to 3). The evaluation of the applicability of the Frumkin and Temkin adsorption isotherms over the same potential range is described elsewhere.\(^7\)

The cathodic HER at the Pt group metal interfaces is one of the most extensively studied topics in electrical engineering.
using Eq. 5. The Temkin adsorption isotherms corresponding to the Frumkin adsorption isotherms are labeled c. Note that the values of \( g \) and \( K_o \) for the Temkin adsorption isotherms are approximately 4.6 and 10 times greater than those for the correlated Frumkin adsorption isotherms, respectively. The Temkin adsorption isotherms are valid and effective only at 0.2 < \( \theta \) < 0.8.

As shown in Figs. 1 to 3, \( g \) for the Temkin adsorption isotherm can be simply determined by the slope of experimental data for 0.2 < \( \theta \) < 0.8. This implies that the two different adsorption isotherms, i.e., the Temkin and Frumkin or Langmuir adsorption isotherms, appear to fit the same data regardless of their adsorption conditions. Correspondingly, the physical meaning of \( g \) for the Temkin adsorption isotherm is clearly different from that for the Frumkin adsorption isotherm regardless of their mathematical approximations. In other words, \( g \) for the Temkin adsorption isotherm (Eq. 5) does not imply the correct lateral interaction between the UPD H or OPD H species. This is the reason why the applicability and its limitations of the Temkin adsorption isotherms for UPD H and OPD H should be considered at the Pt group metal interfaces. The \( g \) and \( K \) for the Temkin adsorption isotherms of OPD H at noble metal interfaces are summarized elsewhere. 7.

As stated above, we have experimentally and consistently found and confirmed that the equilibrium constants \( (K_o) \) for the Temkin adsorption isotherms are approximately 10 times greater than those \( (K_o \) or \( K \)) for the correlated Frumkin or Langmuir adsorption isotherms. 7,11,12 These factors (ca. 4.6 and 10) can be taken as correlation constants between the Temkin and Frumkin or Langmuir adsorption isotherms. Finally, one can conclude that the Temkin adsorption isotherm of UPD H correlating with the Frumkin or Langmuir adsorption isotherm of UPD H, and vice versa, is readily determined using the correlation constants. The electrode kinetic data \( (g, \ K_o, \ K) \) for the Temkin adsorption isotherms \( (\theta \ vs. \ E) \) of UPD H at the Pt(111), Pt(100), Pt, and Rh interfaces are readily determined using the correlation constants and are summarized in Table 2.

Fig. 2. Comparison of the Frumkin and four fitted Temkin adsorption isotherms at the Ir/0.5 M H\(_2\)SO\(_4\) aqueous solution interface (adapted from Ref. 11). All potentials \( (E) \) are given on the standard hydrogen electrode (SHE) scale. Experimental data: ■. The solid curve shows the Frumkin adsorption isotherm, i.e., \( K = 2.7 \times 10^{-5} \exp(2.4\theta) \ \text{mol}^{-1} \), calculated using Eq. 4. Dashed lines show the Temkin adsorption isotherms calculated using Eq. 5 and the correlation constants for (a) \( g = -4 \), (b) \( g = 0 \), (c) \( g = 2.2 \), and (d) \( g = 6.2 \) with \( K_o = 2.7 \times 10^{-4} \ \text{mol}^{-1} \). Note that the Temkin adsorption isotherm, i.e., \( K = 2.7 \times 10^{-4} \exp(-2.2\theta) \ \text{mol}^{-1} \), is valid and effective only at 0.2 < \( \theta \) < 0.8.

Fig. 3. Comparison of the Frumkin and four fitted Temkin adsorption isotherms at the Pd/0.5 M H\(_2\)SO\(_4\) aqueous solution interface (adapted from Ref. 12). All potentials \( (E) \) are given on the standard hydrogen electrode (SHE) scale. Experimental data: ■. The solid curve shows the Frumkin adsorption isotherm, i.e., \( K = 3.3 \times 10^{-5} \exp(-1.6\theta) \ \text{mol}^{-1} \), calculated using Eq. 4. Dashed lines show the Temkin adsorption isotherms calculated using Eq. 5 and the correlation constants for (a) \( g = -4 \), (b) \( g = 0 \), (c) \( g = 6.2 \), and (d) \( g = 15.2 \) with \( K_o = 3.3 \times 10^{-4} \ \text{mol}^{-1} \). Note that the Temkin adsorption isotherm, i.e., \( K = 3.3 \times 10^{-4} \exp(-6.2\theta) \ \text{mol}^{-1} \), is valid and effective only at 0.2 < \( \theta \) < 0.8.
4. Interaction parameter for the Frumkin adsorption isotherm

At the Pt(111), Pt(100), Pt, and Rh interfaces, the positive values of $g$ for the Frumkin adsorption isotherms shown in Table 2 imply the lateral repulsive interaction between the UPD H species, which leads to a decrease in the absolute value of the standard Gibbs energy ($\Delta G^0_\theta$) of UPD H with $\theta$ ($0 \leq \theta \leq 1$) (see Table 1). Note that $\Delta G^0_\theta$ is a negative number, i.e. $\Delta G^0_\theta < 0$.

At Pt, Ir, and Pt-Ir alloy interfaces, the negative values of $g$ for the Frumkin adsorption isotherms imply the lateral attractive interaction between the OPD H species, which leads to an increase in $\Delta G^0_\theta$ of OPD H with $\theta$ ($0 \leq \theta \leq 1$). This is a unique feature of OPD H species at the Pt group metal interfaces. However, the lateral attractive interaction ($g < 0$) between the OPD H species at the Pt, Ir, and Pt-Ir alloy interfaces is significantly different from the lateral repulsive interaction ($g > 0$) between the OPD H species at a Pd interface even though the Pd belongs to the Pt group metals. This aspect is frequently overlooked and confused in the Temkin adsorption isotherm of OPD H at the Pt group metal interfaces.

5. Conclusions

At the Pt(111), Pt(100), Pt, and Rh interfaces, the electrode kinetic data ($g$, $K_o$, $K$) for the Frumkin and Temkin adsorption isotherms ($\theta$ vs. $E$) of UPD H are readily determined using the standard Gibbs energy of adsorption ($\Delta G^0_\theta$) and the correlation constants. The lateral repulsive interaction ($g > 0$) between the UPD H species at the Pt(111), Pt(100), Pt, and Rh interfaces is significantly different from the lateral attractive interaction ($g < 0$) between the OPD H species at the Pt, Ir, and Pt-Ir alloy interfaces. The lateral attractive interaction ($g < 0$) between the OPD H species is a unique feature of the Pt, Ir, and Pt-Ir alloy interfaces. The lateral repulsive interaction ($g > 0$) between the OPD H species is a unique feature of the Pd interface.

For $0.2 < \theta < 0.8$, the two different adsorption isotherms, i.e., the Temkin and Frumkin or Langmuir adsorption isotherms, appear to fit the same data regardless of their adsorption conditions. The physical meaning of $g$ for the Temkin adsorption isotherm is clearly different from that for the Frumkin adsorption isotherm. The applicability and its limitations of the Temkin adsorption isotherms for UPD H and OPD H should be considered at the Pt group metal/aqueous solution interfaces. The Temkin adsorption isotherm correlating with the Frumkin or Langmuir adsorption isotherm, and vice versa, is readily determined using the correlation constants.
