A THEORY OF RESTRICTED
REGULARITY OF HYPERMAPS

ANTONIO BREA D’AZEVEDO

ABSTRACT. Hypermaps are cellular embeddings of hypergraphs in compact and connected surfaces, and are a generalisation of maps, that is, 2-cellular decompositions of closed surfaces. There is a well known correspondence between hypermaps and co-compact subgroups of the free product Δ = C2 ⋊ C2 ⋊ C2. In this correspondence, hypermaps correspond to conjugacy classes of subgroups of Δ, and hypermap coverings to subgroup inclusions. Towards the end of [9] the authors studied regular hypermaps with extra symmetries, namely, G-symmetric regular hypermaps for any subgroup G of the outer automorphism Out(Δ) of the triangle group Δ. This can be viewed as an extension of the theory of regularity. In this paper we move in the opposite direction and restrict regularity to normal subgroups Θ of Δ of finite index. This generalises the notion of regularity to some non-regular objects.

1. Introduction

Regularity has always been present in geometry, often in the form of regular polyhedra or regular tessellations. Well known examples are the nine regular polyhedra comprising the five Platonic solids (the convex regular polyhedra) and the Kepler-Poinsot polyhedra. These polytopes can be viewed as regular maps, that is, cellular decompositions of closed surfaces. In the past two centuries there has been growing interest in highly symmetric maps mainly due to their connections with group theory, elliptic functions, the four colour problem, Riemann surfaces, Galois

theory and algebraic curves, among others. Excellent accounts linking regular maps with some different fields of mathematics can be found in the surveys of Jones [18], Jones and Singerman [21], Nedela [24] and Sirán [26]. After the famous Belyi theorem saying that “A Riemann surface $X$ is defined over the algebraic numbers $\mathbb{Q}$ if and only if there is a covering (now called the Belyi function) from $X$ to $\mathbb{C}$ unramified outside $0, 1$ and $\infty$” [2] and the remarkable observation by Grothendieck [16] that the pre-image set $f^{-1}([0, 1]) \subset X$ of a such Belyi function $f$ is a bipartite graph cellularly embedded on the surface $X$ (and hence a hypermap), there has been a growing interest in the hypermap theory.

Regularity has had different meanings in history. For example, uniformity (that is, vertices, edges and faces having constant valencies, say $l$, $m = 2$ and $n$, respectively) has been taken for regularity in the early studies of regular polyhedra of genus one and two by Errera [14]. Although this weak form of regularity is enough to describe other “strong forms” of regularity in the sphere (“rotary”, “reflexible”), this feature is exclusive to this surface; no other compact orientable surface has a similar behaviour. As noticed by Brahan in [3], for a surface of genus one (Anchor Ring) it gives only a certain measure of “regularity” (read “orientable regularity”). But Brahan himself took regularity to mean “orientable regularity” (that is, “rotary” or “orientable direct regularity”). There is a large number of papers on regular (or reflexible) maps, hypermaps and polytopes published in the 20th century. Most of the papers dealing with non-regularity are directly or indirectly dealing with some form of a lesser degree of regularity.

In this paper we introduce a restricted form of regularity that casts light upon some of the weaker forms of regularity studied earlier. In [22] and [9] one finds a study of regular maps and hypermaps with extra symmetries, namely, the $\text{Out}(\Delta(\infty, \infty, 2))$-symmetric regular maps and $\text{Out}(\Delta)$-symmetric regular hypermaps, respectively. These are regular (hyper)maps which are invariant with respect to the outer automorphisms. This can be viewed as an extension of the theory of regularity. In this paper we explore the opposite direction and propose to restrict the study of regularity to subgroups of $\Delta$. We set up the notion of $\Theta$-regularity for any normal subgroup $\Theta$ of $\Delta$ with finite index, widening this way the notion of regularity to include some (not all) non-regular hypermaps as “regular” hypermaps in some sense.

Reduced regularity is not at all new. An orientably regular map (or hypermap) is the most known restricted form of regularity, in this case restricted to orientation preserving automorphisms ($\Delta^+$-regularity).
Less familiar is the orientable bipartite-regularity that appeared in the medial maps of regular oriented maps studied by Archdeacon, Širáň and Škoviera [1], an orientable regularity restricted to bipartite-face-preserving automorphisms. Among the 14 automorphism types of edge-transitive maps classified by Graver and Watkins [15], and referred by Siran, Tucker and Watkins in [27], 11 correspond to restrictively regular maps. Other forms of restricted regularity can be found in older literature, though not directly. Some maps appearing as geometrical illustrations of groups in Burnside’s monograph [11] (and also in Dyck [13]) are non-regular (in the “reflexible” and “orientable” sense), and even non-uniform. For example, Fig. 10 in the Burnside’s book [11] illustrates a non-regular map which is \( \langle R_2, (R_0 R_1)^3 \rangle^\Delta \) -regular in our restricted sense of regularity.

The structure of the paper is organised as follows. In the last three subsections of the introductory part we give a brief introduction to the theory of hypermaps. For a deep introduction on maps/hypermaps we refer the reader to [4, 9, 10, 12, 19, 21]. Section 2 is dedicated to \( \Theta \)-conservative hypermaps, a generalisation of “orientable hypermaps” (\( \Delta^+ \)-conservative hypermaps), and to \( \Theta \)-regularity; some classic results in the theory of hypermaps are generalised here. The main topic of section 3 is related to the monodromy group of a \( \Theta \)-conservative hypermap. Some concepts are generalised, for example, the “even word subgroup” \( \text{Mon}^+ (H) \) of the monodromy group \( \text{Mon}(H) \) of an orientable hypermap \( H \) generalises to \( \Theta \)-word subgroup \( \text{Mon}^{\Theta} (H) \) of the monodromy group of a \( \Theta \)-conservative hypermap \( H \). The \( \Theta \)-monodromy group of a \( \Theta \)-conservative hypermap is introduced; relative to the even word subgroup \( \text{Mon}^+ (H) = \langle R, L \rangle \), the \( \Delta^+ \)-monodromy group is just the group generated by the restrictions of \( R \) and \( L \) to one of the two orbits inducing the two orientations of the underlying orientable surface. Section 4 deals with the notion of \( \Theta \)-marked hypermaps, a generalisation of “oriented hypermaps” (\( \Delta^+ \)-marked hypermaps). The relationship between \( \Theta \)-hypermaps and \( \Theta \)-conservative hypermaps is explored in section 5. Section 6 introduces \( \Theta \)-slices, the \( \Theta \)-regions corresponding to “flags” (\( \Delta \)-slices) in hypermaps and “darts” (\( \Delta^+ \)-slices) in oriented hypermaps. Section 7 illustrates, on an example, the construction of a regular \( \Theta \)-marked hypermap with a given group as monodromy group. In section 8 we treat \( \Theta \)-regularity in terms of regular coverings and in section 9 we introduce \( \Theta \)-type and derive a formula for computing the characteristic of a \( \Theta \)-regular hypermap. The last section (section 10) is devoted to answering the question of when a hypermap can be “restrictly” regular.
or not. Families of non-regular maps that are restrictly and not restrictly regular are given.

1.1. Hypermaps

A (algebraic) hypermap is a four-tuple $\mathcal{H} = (F; r_0, r_1, r_2)$ consisting of a non-empty finite set $F$, the set of flags, and three permutations $r_0, r_1, r_2$ of $F$ satisfying $r_0^2 = r_1^2 = r_2^2 = 1$ and generating a permutation group $\text{Mon}(\mathcal{H}) = \langle r_0, r_1, r_2 \rangle$, called the monodromy (or $\Delta$-monodromy) group of $\mathcal{H}$, that acts transitively on $F$. If one of the $r_i$'s has fixed points then $\mathcal{H}$ has boundary, otherwise $\mathcal{H}$ is boundary-free. The transitive action implies $|\text{Mon}(\mathcal{H})| \geq |F|$. Every hypermap corresponds to a cellular embedding of a hypergraph $G$ in $S$, also called a topological hypermap. Conversely, every topological hypermap can be described by a four-tuple $\mathcal{H} = (F; r_0, r_1, r_2)$ introduced above.

A covering from $\mathcal{H}$ to $\mathcal{H}' = (F'; s_0, s_1, s_2)$ is a function $\psi : F \rightarrow F'$ satisfying $r_i \psi = \psi s_i$ for $i = 0, 1, 2$. Due to the transitivity of the the actions, every covering is necessarily surjective. An isomorphism is an injective covering. If $\psi$ is a covering then the assignment $r_i \mapsto s_i$ extends to a canonical epimorphism from $\text{Mon}(\mathcal{H})$ to $\text{Mon}(\mathcal{H}')$. An automorphism of $\mathcal{H}$ is an isomorphism from $\mathcal{H}$ to $\mathcal{H}$, that is, a permutation of $F$ commuting with each $r_i$, hence commuting with every $g \in \text{Mon}(\mathcal{H})$. The automorphisms of $\mathcal{H}$ form a group $\text{Aut}(\mathcal{H})$ that acts semi regularly on $F$. As a consequence, $|\text{Aut}(\mathcal{H})| \leq |F|$, and hence we have

$$|\text{Aut}(\mathcal{H})| \leq |F| \leq |\text{Mon}(\mathcal{H})|.$$  

An equality on one side implies an equality on the other side. This happens if and only if the action of $\text{Aut}(\mathcal{H})$ on $F$ is regular. In this case $\mathcal{H}$ is called a regular hypermap.

The type of a hypermap $\mathcal{H}$ is a triple $(k; l; m)$, where $k$, $l$, and $m$ are the least common multiple of valencies of hypervertices, hyperedges and hyperfaces respectively. A map of type $(m, k)$ is a hypermap of type $(k; 2; m)$. Denoting by $\mathcal{V}$, $\mathcal{E}$ and $\mathcal{F}$ the set of hypervertices, hyperedges and hyperfaces of a boundary-free hypermap $\mathcal{H}$ (respectively), then the characteristic $\chi(\mathcal{H})$ of $\mathcal{H}$, that is, the characteristic of the underlying surface, is given by the well known formula,

$$\chi(\mathcal{H}) = |\mathcal{V}| + |\mathcal{E}| + |\mathcal{F}| - \frac{|F|}{2}.$$
1.2. Finite permutation representation of hypermaps

Let \( \Delta \) denote the free product \( C_2 \ast C_2 \ast C_2 \) with presentation \( \langle R_0, R_1, R_2 \mid R_0^2=R_1^2=R_2^2=1 \rangle \). There is a natural epimorphism \( \rho: \Delta \twoheadrightarrow \text{Mon}(\mathcal{H}) \) taking \( R_i \to r_i \). This epimorphism induces an action \( w \cdot d := wdp \) of \( \Delta \) on \( F \). Fixing a flag \( w \in F \), let \( H \) be the stabiliser of \( w \) in \( \Delta \). Then \( \Delta \) acts on the set of right cosets \( \Delta/H \) of \( H \) in \( \Delta \) by right multiplication, and \( \rho \) induces a bijective function \( \rho_w: \Delta/H \to F \), \( Hd \mapsto w \cdot d = wdp \). The kernel of \( \rho \) is \( H^* = H_\Delta \), the core of \( H \) in \( \Delta \). The group \( \Delta/H^* \) acts transitively on \( \Delta/H \) by right multiplication \( (Hd \cdot H^*g = HdH^*g = Hdg) \); this action is similar to the action of the monodromy group \( \text{Mon}(\mathcal{H}) \) on \( F \). Hence the hypermap \( \mathcal{H} \) can be identified with \( (\Delta/H; H^*R_0, H^*R_1, H^*R_2) \), having monodromy group \( \Delta/H_\Delta \cong \text{Mon}(\mathcal{H}) \). The subgroup \( H \) of \( \Delta \) is a fundamental subgroup of \( \mathcal{H} \). This is independent up to a conjugation in \( \Delta \). The automorphism group \( \text{Aut}(\mathcal{H}) \) can be identified with \( N_\Delta(H)/H \) acting on the set of right cosets \( F = \Delta/H \) (the set of flags) from the left, that is,

\[ \forall \ Hg \in N_\Delta(H)/H, \forall d \in \Delta/H, \ Hd \cdot Hg = Hg^{-1}d. \]

Any automorphism \( \psi \in \text{Aut}(\mathcal{H}) \) is then a function \( \phi_g: Hd \mapsto Hg^{-1}d \), for some \( g \in N_\Delta(H) \). The semi-regularity of the action says that if \( Hd \phi_g = Hd \) then \( g \in H \).

The two groups \( H^* = H_\Delta \), the core of \( H \) in \( \Delta \), and \( H^\Delta = \langle H \rangle^\Delta \), the normal closure of \( H \) in \( \Delta \), give rise to two regular hypermaps, the covering core \( \mathcal{H}_\Delta \) and the closure cover \( \mathcal{H}^\Delta \), with the inclusions \( H_\Delta < H < H^\Delta \) determining a covering lattice \( \mathcal{H}_\Delta \to \mathcal{H} \to \mathcal{H}^\Delta \).

2. \( \Theta \)-conservative and \( \Theta \)-regular hypermaps

Let \( \Theta \) be a normal subgroup with finite index \( n \) in \( \Delta \). We say that a hypermap \( \mathcal{H} \) is \( \Theta \)-conservative if its fundamental subgroup \( H \) is a subgroup of \( \Theta \). It is clear that if \( \mathcal{H} \) is \( \Theta \)-conservative then so are its covering core \( \mathcal{H}_\Delta \) and its closure cover \( \mathcal{H}^\Delta \).

**Theorem 1.** Let \( \Theta \) be a normal subgroup of index \( n \) in \( \Delta \). If \( \mathcal{H} \) is \( \Theta \)-conservative, then

1. \( \Theta \) acts by right multiplication on \( F \) with \( n \) orbits;
2. the action of \( \Theta \) on \( F \) is uniform (all orbits have the same length).

**Proof.** (1) Naturally that \( \Delta \) acts by right multiplication on \( F = \Delta/H \) and, consequently, the subgroup \( \Theta \) also acts by right multiplication.
on $F$. Each orbit (under the action of $\Theta$) is a set of the form $Hd\Theta = \{Hdt \mid t \in \Theta\}$. Let $\mathcal{O}_\Theta$ denote the set of orbits $\{Hd\Theta \mid Hd \in F\}$. The function $\psi : \Delta/\Theta \rightarrow \mathcal{O}_\Theta$, $\Theta d \mapsto Hd\Theta$, is obviously onto, is well defined,

$$\Theta d_1 = \Theta d_2 \Rightarrow d_1^{-1}d_2 = ((d_1d_2^{-1})^{-1})d_2 \in \Theta, \quad \text{since} \quad \Theta \triangleleft \Delta,$$

$$\Rightarrow Hd_1(d_1^{-1}d_2) = Hd_2 \in Hd_1\Theta$$

$$\Rightarrow Hd_1\Theta = Hd_2\Theta,$$

and is one-one,

$$Hd_1\Theta = Hd_2\Theta \Rightarrow Hd_2 = Hd_1g, \quad \text{for some} \ g \in \Theta,$$

$$\Rightarrow \Theta d_1gd_2^{-1} = \Theta d_1d_2^{-1} = \Theta$$

$$\Rightarrow \Theta d_1 = \Theta d_2.$$

(2) Let $H\Theta, Hd_1\Theta, \ldots, Hd_{n-1}\Theta$ be the $n$ orbits. As $Hgd_i = Hd_i d_i^{-1}$

$gd_i = Hd_i g d_i \in Hd_i\Theta$, the function $\psi : \Theta \rightarrow Hd_i\Theta$, $Hg \mapsto Hgd_i$ is

clearly well defined and injective. For any $Hd_i g \in Hd_i\Theta$, $g d_i^{-1} \in \Theta$ and so

$Hg d_i^{-1}\psi = Hg d_i^{-1}d_i = Hd_ig$, which shows that $\psi$ is onto. □

These $n$ orbits, which can be understood as $n$ flag-colourings, will be called $\Theta$-orbits. If $\omega = Hb$ is a flag, the $\Theta$-orbit determined by $\omega$

will be denoted indistinctly by $\omega\Theta$ or by $F_b^\Theta$. Denote by $F_b^\Theta$ the orbit $F_b^\Theta$
determined by the flag $H$. Notice that the normality of $\Theta$ in $\Delta$
allows us to write $F_b^\Theta = \{Htb \mid t \in \Theta\}$. The reason for the last

notation is to bring it closer to the standard notation of $F^+$ and $F^-$

used in some literature to mean the two orbits $\omega\Delta^+$ and $\omega\Delta^-$ of an orientable map/hypermap.

Some $\Theta$-conservative maps/hypermaps are very familiar although not under this name. For example, an orientable hypermap is a $\Delta^+$-conservative hypermap, where $\Delta^+$ is the even word subgroup of $\Delta$, i.e., the normal closure $\langle R_1R_2, R_2R_0 \rangle^\Delta$ in $\Delta$; a bipartite hypermap is a $\Delta^0$-conservative hypermap, where $\Delta^0$ is the normal closure $\langle R_1, R_2 \rangle^\Delta$ of index 2 in $\Delta$; a pseudo-orientable hypermap (Wilson [28]) is a $\Delta^0$-conservative hypermap, where $\Delta^0$ is the normal closure $\langle R_0, R_1R_2 \rangle^\Delta$, also a subgroup of index 2 in $\Delta$.

**Lemma 2.** If $T = \{1 = b_1, \ldots, b_n\}$ is a transversal for $\Theta$ in $\Delta$, then $F_{b_1}^\Theta, \ldots, F_{b_n}^\Theta$ are the $n$ orbits of the action of $\Theta$ on $F$.

**Proof.** The flags $Hb_1, \ldots, Hb_n$ belong to distinct orbits. In fact, for $t \in \Theta$, $Hb_i = Hb_j t$ implies that $b_j t b_i^{-1} \in H \subset \Theta$, which implies that $\Theta b_i = \Theta b_j t \leftrightarrow \Theta b_i = \Theta b_j \leftrightarrow b_i = b_j$. □
The following theorem states that both the monodromy group and the automorphism group of a $\Theta$-conservative hypermap act on the set of $\Theta$-orbits $O_{\Theta}$.

**Theorem 3.** If $H$ is a $\Theta$-conservative hypermap, then (1) the monodromy group $\text{Mon}(H)$ acts transitively on the set of $\Theta$-orbits $O_{\Theta}$ by right multiplication ($F^\Theta_b \cdot H \Delta g = F^\Theta_{bg}$), (2) the automorphism group $\text{Aut}(H)$ acts (not necessarily transitively) on $O_{\Theta}$ by $\omega \Theta \psi = \omega \psi \Theta$.

**Proof.** (1) For any $g \equiv H \Delta g \in \Delta(H)$ and for any orbit $F^\Theta_b \in O_{\Theta}$,

\[
F^\Theta_b \cdot g = F^\Theta_b \Delta g = \{ Hbgt \mid t \in \Theta \} = \{ Hbg t' \mid t' = tg \in \Theta^g = \Theta \} = F^\Theta_{bg}.
\]

(2) Let $\omega = Hb \in \Delta(H)$ be a flag and $\omega \cdot \Theta = F^\Theta_b$ be the $\Theta$-orbit determined by $\omega$. For any automorphism $\psi \in \text{Aut}(H) = N_\Delta(H)/H$, $\psi$ is a function $\phi_g : Hb \mapsto Hg^{-1}b$, for some $g \in N_\Delta(H)$. Since $Hb \Theta \phi_g = Hg^{-1}b \Theta$ it follows $F^\Theta_b \phi_g = F^\Theta_{g^{-1}b}$, that is, $\omega \Theta \psi = \omega \psi \Theta$. $\square$

Denote by $\text{Aut}^\Theta(H)$ the subset of $\text{Aut}(H)$ consisting of the automorphisms preserving each $\Theta$-orbit $F^\Theta_{b_i}$, $i = 1, \ldots, n$. This group will be called the $\Theta$-automorphism group of $H$.

**Theorem 4.** $\text{Aut}^\Theta(H) = N_{\Theta}(H)/H$.

**Proof.** If $\phi = H\tau \in N_{\Theta}(H)/H$ ($\tau \in \Theta$), then $\phi$ preserves each $\Theta$ orbit $F^\Theta_b$; in fact, $F^\Theta_b \phi = F^\Theta_{\tau^{-1}b} = \{ Ht' b \mid t' = t \tau^{-1} \in \Theta \} = F^\Theta_b$. If $\phi = Hg \in \text{Aut}^\Theta(H) \subset \text{Aut}(H) = N_\Delta(H)/H$, then $\phi$ preserves each orbit $F^\Theta_b \in O_{\Theta}$. In particular $\phi$ preserves the orbit $F^\Theta_1$ determined by $H$, and so, $H \phi \in F^\Theta_1$, that is, $Hg^{-1} = Ht$ for some $t \in \Theta$. Hence $g \in \Theta$ and $\phi = Hg \in N_{\Theta}(H)/H$. $\square$

We say that $H$ is $\Theta$-regular if $\text{Aut}^\Theta(H)$ acts transitively on each $\Theta$-orbit $F^\Theta_{b_1}, \ldots, F^\Theta_{b_n}$.

**Theorem 5.** If $\text{Aut}^\Theta(H)$ acts transitively on a $\Theta$-orbit $F^\Theta_{b_1}$, then $\text{Aut}^\Theta(H)$ acts transitively on any other $\Theta$-orbit.

**Proof.** Let us show that if $\text{Aut}^\Theta(H)$ acts transitively on the orbit $F^\Theta_d$ then $\text{Aut}^\Theta(H)$ acts transitively on the orbit $F^\Theta_1$. For any $t \in \Theta$, there
is $\phi_g = Hg \in N_{\Theta}(H)/H = \text{Aut}^\Theta(\mathcal{H})$ such that $Hd(d^{-1}td) = Hd\phi_g = Hg^{-1}d$, that is, $Ht = Hg^{-1} = H\phi_g$. Hence $\text{Aut}^\Theta(\mathcal{H})$ acts transitively on $F_1^\Theta$. To finish the proof we show that if $\text{Aut}^\Theta(\mathcal{H}) = N_{\Theta}(H)/H$ acts transitively on the orbit $F_1$ then it acts transitively on any orbit $F_d^\Theta$.

For any $t \in \Theta$, there is $\phi_g = Hg \in N_{\Theta}(H)/H = \text{Aut}^\Theta(\mathcal{H})$ such that $H(dtd^{-1}) = H\phi_g = Hg^{-1}$. But this is equivalent to $Hdt = Hg^{-1}d = H\phi_g$.

THEOREM 6. $\mathcal{H}$ is $\Theta$-regular if and only if $H$ is a normal subgroup of $\Theta$.

Proof. $(\Leftarrow)$ If $H \triangleleft \Theta$, then $N_{\Theta}(H) = \Theta$ and so, for any $t \in \Theta$, $Ht = H\phi_{t^{-1}}$, that is, $\Theta/H = N_{\Theta}(H)/H = \text{Aut}^\Theta(\mathcal{H})$ acts transitively on the orbit $F_1^\Theta$.

$(\Rightarrow)$ If $\text{Aut}^\Theta(\mathcal{H}) = N_{\Theta}(H)/H$ acts transitively on the orbit $F_1^\Theta$, then for any $t \in \Theta$, there is $g \in N_{\Theta}(H)$ such that $Ht = H\phi_g = Hg^{-1}$. This says that $t \in Hg^{-1} \subset RN_{\Theta}(H) = N_{\Theta}(H)$. Hence $\Theta \subset N_{\Theta}(H) \iff N_{\Theta}(H) = \Theta$. □

Often, regularity in map/hypermap theory appears in the form of $\Delta$-regular (or simply regular) and $\Delta^+$-regular. Depending on the context, $\Delta^+$-regular has been known as “rotary”, “directly regular” or “orientably regular”. Less usual is $\Delta^0$-regular, or “bipartite-regular”.

3. $\Theta$-monodromy group

The action of $\Theta$ on the set of flags $F$ of a $\Theta$-conservative hypermap $\mathcal{H}$ induces a natural homomorphism (not onto) $\alpha$ from $\Theta$ to the symmetric group $\text{Sym}(F)$. The image $\text{Im}(\alpha) = \Theta \alpha$ is a subgroup of $\text{Mon}(\mathcal{H})$. Call it the $\Theta$-word subgroup and denote it by $\text{Mon}^\Theta(\mathcal{H})$. In an orientable hypermap the $\text{Mon}^{\Delta^+}(\mathcal{H})$ is just the “even” word subgroup generated by the “even” words $H_\Delta R_1 R_2, H_\Delta R_2 R_0$.

LEMMA 7. $\text{Mon}^\Theta(\mathcal{H}) \cong \Theta/H_\Delta$ and $\text{Mon}^\Theta(\mathcal{H}) \triangleleft_n \text{Mon}(\mathcal{H})$.

Proof. The kernel $\text{Ker}(\alpha)$ is the core of $H$ in $\Delta$. Moreover, $\Theta/H_\Delta \triangleleft_n \Delta/H_\Delta \cong \text{Mon}(\mathcal{H})$. □

Now, $\Theta$ also acts (by right multiplication) on each $\Theta$-orbit $F_b^\Theta$ ($b \in T$). This gives rise to a homomorphism $\alpha_b : \Theta \longrightarrow \text{Sym}(F_b^\Theta)$, $t \longmapsto t\alpha_b : Hb \longmapsto Hbxt$. We denote by $\Theta_{-}\text{Mon}_b(\mathcal{H})$ the subgroup $\text{Im}(\alpha_b) =$
\(\Theta \alpha_\Theta \subset \text{Sym}(F_b^\Theta)\) and call it the \(\Theta\)-monodromy group of \(\mathcal{H}\) on \(F_b^\Theta\). In particular, the \(\Theta\)-monodromy of \(\mathcal{H}\) on the orbit \(F_1^\Theta\) will be simply called \(\Theta\)-monodromy group of \(\mathcal{H}\) and will be denoted by \(\Theta\)-Mon(\(\mathcal{H}\)).

**Theorem 8.** \(\Theta\)-Mon\(_b\)(\(\mathcal{H}\)) is isomorphic to \(\Theta/H_b^\Theta\).

*Proof.* In fact, the kernel \(\text{Ker}(\alpha_\Theta)\) is the core of \(H_b\) in \(\Theta\). \(\square\)

On different \(\Theta\)-orbits the action of \(\Theta\) may not be equivalent, however, they induce isomorphic groups.

**Theorem 9.** For any \(b \in T\), \(\Theta\)-Mon\(_b\)(\(\mathcal{H}\)) is isomorphic to \(\Theta\)-Mon(\(\mathcal{H}\)) \(\cong \Theta/H_b^\Theta\).

*Proof.* In fact, from the normality of \(\Theta\) in \(\Delta\) we deduce

\[
\Theta\text{-Mon}_b(\mathcal{H}) \cong \Theta/H_b^\Theta = (\Theta/H_b)^b \cong \Theta/H_b \cong \Theta\text{-Mon}(\mathcal{H}).
\]

\(\square\)

**Corollary 10.** If \(\mathcal{H}\) is \(\Theta\)-regular, then \(1\) \(\Theta\)-Mon(\(\mathcal{H}\)) \(\cong \Theta/H\); \(2\) \(|F| = |\Delta : \Theta||\Theta\text{-Mon}(\mathcal{H})| = n|\Theta\text{-Mon}(\mathcal{H})|\).

The semi-regular action of \(\text{Aut}^\Theta(\mathcal{H})\) and the transitive action of \(\Theta\)-Mon(\(\mathcal{H}\)) on the set of \(\Theta\)-orbits \(F^\Theta\) of a \(\Theta\)-conservative hypermap \(\mathcal{H}\) give the following chain of inequalities,

\[
|\text{Aut}^\Theta(\mathcal{H})| \leq |F^\Theta| \leq |\Theta\text{-Mon}(\mathcal{H})|.
\]

**Theorem 11.** The following statements are equivalent:

1. \(\mathcal{H}\) is \(\Theta\)-regular;
2. \(|\text{Aut}^\Theta(\mathcal{H})| = |F^\Theta| \); 3. \(|F^\Theta| = |\Theta\text{-Mon}(\mathcal{H})|\).

*Proof.* \(\mathcal{H}\) is \(\Theta\)-regular \(\iff H \triangleleft \Theta \iff H_b = H \iff N_\Theta(H)/H = \Theta/H\).

By Theorem 9, \(\Theta\)-Mon(\(\mathcal{H}\)) \(\cong \Theta/H_b\) and by Theorem 4, \(\text{Aut}^\Theta(\mathcal{H}) = N_\Theta(H)/H\). Hence \(\mathcal{H}\) is \(\Theta\)-regular \(\iff \text{Aut}^\Theta(\mathcal{H}) \cong \Theta/H \iff |\text{Aut}^\Theta(\mathcal{H})| = |F^\Theta|\). Similarly, \(|F^\Theta| = |\Theta\text{-Mon}(\mathcal{H})| \iff |\Theta : H_b| = |\Theta : H_b| \iff H_b = H \iff \mathcal{H}\) is \(\Theta\)-regular. \(\square\)

For each \(t \in \Theta\), the permutation \(t\alpha_\Theta\) is essentially the action of \(t\) on \(F_b^\Theta\). Hence it makes sense to denote by \(t_{F_b^\Theta}\) the permutation \(t\alpha_\Theta\).

Having this in mind, we can write

\[
\Theta\text{-Mon}(\mathcal{H}) = \Theta|_{F_b^\Theta},
\]

and rewrite theorem 9 as follows: for each orbit \(F_b^\Theta\), \(\Theta|_{F_b^\Theta} \cong \Theta|_{F_b^\Theta}\).
4. \( \Theta \)-marked hypermaps

As \( \Theta \) has finite index in a finite generated group \( \Delta \), by Nielsen-Schreier theorem \( \Theta \) is also finitely generated. Moreover, as \( \Delta \) is a free product \( C_2 \ast C_2 \ast C_2 \), by Kurosh theorem (Proposition 3.6, p.120 of [23]) \( \Theta \) is also a free product \( \Theta \cong C_2 \ast \cdots \ast C_2 \ast C_\infty \ast \cdots \ast C_\infty \), for a certain number of factors \( C_2 \) and \( C_\infty \), where the number of factors of one type \( (C_2 \text{ or } C_\infty) \) may be empty. According to the above free-product decomposition (which is unique up to a permutation of its factors),

\[
\Theta = \langle a_1, \ldots, a_s, z_1, \ldots, z_t \mid a_i^2 = 1, i = 1 \ldots s \rangle.
\]

Let \( \text{rank}(\Theta) = m \). For simplicity, put \( \{x_1, \ldots, x_m\} = \{a_1, \ldots, a_s, z_1, \ldots, z_t\} \). If there are factors \( C_2 \) in the above free-product decomposition, we write them first, so we expect involutions coming first in the above generator’s set.

By a \( \Theta \)-marked hypermap we mean a \((m+1)\)-tuple

\[
Q = (\Omega; \alpha_1, \ldots, \alpha_m),
\]

where \( \Omega \) is a finite set, \( \alpha_1, \ldots, \alpha_m \) are permutations of \( \Omega \) generating a group \( G \) acting transitively on \( \Omega \) such that the function \( \rho: x_i \mapsto \alpha_i \) extends to an epimorphism from \( \Theta \) to \( G \). This group \( G \) is the monodromy group of \( Q \) and will be denoted by \( \text{Mon}(Q) \). The name “marked hypermap” was chosen because the triple \((G, \Omega, D)\), where \( D = \{\alpha_1, \ldots, \alpha_m\} \), is a marked finite transitive permutation group (Singerman [25]). The epimorphism \( \rho \) induces a transitive action of \( \Theta \) on \( \Omega \) defined by \( w \cdot d := w \cdot (d \rho) \), for all \( d \in \Theta \). For a fixed \( w \in \Omega \), let \( Q \) be the stabiliser of \( w \) in \( \Theta \). Then \( \Theta \) acts by right multiplication on the right cosets \( \Theta/Q \) and \( \rho \) induces a bijective function \( \rho_w: \Theta/Q \longrightarrow \Omega, \text{Qd} \mapsto \text{wd}\rho \). The kernel of \( \rho \) is the core \( Q_\phi \) of \( Q \) in \( \Theta \). The group \( \Theta/Q_\phi \) (which is isomorphic to \( G \) by \( \rho \)) acts transitively on \( \Theta/Q \) by right multiplication \((Qd \cdot Q_\phi g = Qdg)\) and this action is similar to the action of \( G = \text{Mon}(Q) \) on \( \Omega \); that is, the following diagram

\[
\begin{array}{c}
\Theta/Q \times \Theta/Q_\phi & \longrightarrow & \Theta/Q \\
\rho_w \downarrow \rho & & \rho_w \\
\Omega \times G & \longrightarrow & \Omega
\end{array}
\]

commutes. The \( \Theta \)-marked hypermap \( Q \) can then be identified with the \( \Theta \)-marked hypermap \((\Theta/Q; Q_\phi x_1, \ldots, Q_\phi x_m)\) with monodromy group \( \Theta/Q_\phi \cong \text{Mon}(Q) \). This subgroup \( Q \) of \( \Theta \) will be called a \( \Theta \)-marked fundamental subgroup of \( Q \). Giving two \( \Theta \)-marked hypermaps \( Q_1 = \)
A theory of restricted regularity of hypermaps

$(\Omega_1; \alpha_1, \ldots, \alpha_m)$ and $Q_2 = (\Omega_2; \beta_1, \ldots, \beta_m)$, a covering from $Q_1$ to $Q_2$ is a function $\phi : \Omega_1 \rightarrow \Omega_2$ (necessarily onto by the transitive action) such that for any $w \in \Omega_1$, $w\alpha_i \phi = w\phi \beta_i$, for $i = 1, \ldots, m$. An isomorphism $\phi : Q_1 \rightarrow Q_2$ is just a one-to-one covering and an automorphism of a $\Theta$-marked hypermap $Q = (\Omega; \alpha_1, \ldots, \alpha_m)$ is an isomorphism from $Q$ to $Q$, that is, a permutation of $\Omega$ commuting with each $\alpha_i$ ($i = 1, \ldots, m$). The above observations prove:

**Theorem 12.** If $Q = (\Omega; \alpha_1, \ldots, \alpha_m)$ is a $\Theta$-marked hypermap, then $Q \cong (\Theta_Q ; Q_\Theta x_1, \ldots, Q_\Theta x_m)$, where $Q$ is the stabiliser in $\Theta$ of any $w \in \Omega$.

As we can observe from the above theorem, the $\Theta$-marked fundamental subgroup $Q$ of $Q$ is independent (up to an isomorphism) from the fixed $w$; different choices of $w$ give rise to conjugate $\Theta$-marked fundamental subgroups (conjugation in $\Theta$), giving rise to isomorphic $\Theta$-marked hypermaps. In fact, given any conjugate $Q'^t$ ($t \in \Theta$) the function $\Theta_Q / Q \rightarrow \Theta_{Q'^t}$ defined by $Qd \mapsto t^{-1}Qd = Q'^td$ is a bijection commuting with each $Q_\Theta x_i$. The group of automorphisms Aut($Q$) of $Q$ is isomorphic to the quotient group $N_G(\text{Stab}_G(w))/\text{Stab}_G(w)$ (Singerman [25]). If $Q$ is the stabiliser of $w$ in $\Theta$, then Aut($Q$) $\cong N_\Theta(Q)/Q$ (Zassenhaus [29], p.51). Definitions and results proved specifically for $\Delta$-marked hypermaps (that is, hypermaps) and $\Delta^+$-marked hypermaps (that is, oriented hypermaps, see for instance [6, 7, 8]) can be adapted to $\Theta$-marked hypermaps. For example, the group of automorphisms Aut($Q$) acts semi-regularly on $\Omega$ giving the double inequality

$$|\text{Aut}(Q)| \leq |\Omega| \leq |\text{Mon}(Q)|.$$

If Aut($Q$) acts transitively (hence regularly) on $\Omega$, then we say that $Q$ is regular. As Aut($Q$) $\cong N_\Theta(Q)/Q$ and $\Omega$ is equipotent to $\Theta/Q$, $Q$ is regular if and only if $Q \triangleleft \Theta$. Moreover, an equality on one side of the above double inequalities implies an equality on the other side. Consequently, the following are equivalent: (1) $Q$ is regular (2) $Q \triangleleft \Theta$, (3) $|\text{Aut}(Q)| = |\Omega|$, (4) $|\text{Mon}(Q)| = |\Omega|$.

5. $\Theta$-marked hypermaps versus $\Theta$-conservative hypermaps

Any $\Theta$-conservative hypermap $H = (F; r_0, r_1, r_2)$, with fundamental subgroup $H < \Theta$, gives rise to $n$ $\Theta$-marked hypermaps

$$H_{F_0} = (F_{r_0}^F ; x_1|_{F_0}, \ldots, x_m|_{F_0}),$$
one for each $\Theta$-orbit $F^\Theta_b$. These special $\Theta$-marked hypermaps will be
called $\Theta$-*hypermaps*. Each $\Theta$-hypermap $\mathcal{H}^\Theta_b$ will be called a “$b$-image”
of
$$\mathcal{H}^\Theta = (F^\Theta; x_1|_{F^\Theta}, \ldots, x_m|_{F^\Theta}).$$

The monodromy group of $\mathcal{H}^\Theta_b$ is the $\Theta$-monodromy group of $\mathcal{H}$ on $F^\Theta_b$,
$$\text{Mon}(\mathcal{H}^\Theta_b) = \langle x_1|_{F^\Theta_b}, \ldots, x_m|_{F^\Theta_b} \rangle = \Theta|_{F^\Theta_b} \cong \Theta/H^b \cong \Theta\cdot\text{Mon}_b(\mathcal{H}).$$

As $\Theta/H^b \cong \Theta/H \cong \text{Mon}(\mathcal{H}^\Theta_b) = \langle x_1|_{F^\Theta_b}, \ldots, x_m|_{F^\Theta_b} \rangle$, the $\Theta$-hypermap
$\mathcal{H}^\Theta$ and its $b$-images $\mathcal{H}^\Theta_b$, $b \in T$, all have the same monodromy group,
$$\text{Mon}(\mathcal{H}^\Theta_b) \cong \text{Mon}(\mathcal{H}^\Theta).$$

However $\mathcal{H}^\Theta$ may not be isomorphic to any of its $b$-images $\mathcal{H}^\Theta_b$. If $\mathcal{H}$
is $\Theta$-regular this translates to “the two monodromy groups $\text{Mon}(\mathcal{H}^\Theta_b)$
and $\text{Mon}(\mathcal{H}^\Theta)$ may not be *monodromically isomorphic* in respect to their
fixed set of generators; that is, the function $x_i|_{F^\Theta} \mapsto x_i|_{F^\Theta_b}$, $i = 1, \ldots, m$,
may not extend to an isomorphism”. In the next theorem we shall show
that if $\mathcal{H}$ is $\Theta$-regular then $\mathcal{H}^\Theta$ is isomorphic to all its $b$-images if and
only if $\mathcal{H}$ is $\Delta$-regular.

**Theorem 13.** A $\Theta$-regular hypermap $\mathcal{H}$ is $\Delta$-regular if and only
if for any $b \in T$, the function $\Theta|_{F^\Theta} \longrightarrow \Theta|_{F^\Theta_b}$, $x|_{F^\Theta} \mapsto x|_{F^\Theta_b}$, is an
isomorphism.

**Proof.** ($\Rightarrow$) Let $\mathcal{H}$ be $\Delta$-regular, which is the same as $H \triangleleft \Delta$. Then
the function
$$\phi: \Theta|_{F^\Theta} \longrightarrow \Theta|_{F^\Theta_b},$$
$$x|_{F^\Theta} \longrightarrow x|_{F^\Theta_b}$$
is well defined and injective; in fact,
$$x_1|_{F^\Theta} = x_2|_{F^\Theta} \iff \forall t \in \Theta, \; Htx_1 = Htx_2$$
$$\iff \forall t \in \Theta, \; x_1x_2^{-1} \in H^t = H^{bt} (= H), \text{ since } H \triangleleft \Delta,$$
$$\iff \forall t \in \Theta, \; Hbtx_1 = Hbtx_2$$
$$\iff x_1|_{F^\Theta_b} = x_2|_{F^\Theta_b}.$$

$\phi$ is obviously onto. Since $x|_A y|_A = (xy)|_A$ the function $\phi$ is obviously a
homomorphism.
(⇐) If, for any \( b \in T \), the function
\[
\phi : \Theta_{|_{F_b^\Theta}} \rightarrow \Theta_{|_{F_b^\Theta}} \\
x_{|_{F_b^\Theta}} \rightarrow x_{|_{F_b^\Theta}}
\]
is an isomorphism then, in particular, it is well defined. As for each \( h \in H \), the permutation \( h_{|_{F_b^\Theta}} : F_b^\Theta \rightarrow F_b^\Theta \), \( Ht \mapsto Hth = tHh = tH = Ht \), is the identity permutation, then for any \( b \in T \),
\[
1_{|_{F_b^\Theta}} = h_{|_{F_b^\Theta}} \iff \forall t \in \Theta, Hbt = Hbth \\
\iff \forall t \in \Theta, h \in H^b \\
\Rightarrow h \in H^b, \text{ by taking } t = 1.
\]
Therefore, \( H \subset H^b \) for any \( b \in T \). As for any \( d \in \Delta, d = tb \) for some \( b \in T \) and \( t \in \Theta \), then \( H^d = H^b \) and so \( H \subset H^d \) for any \( d \in \Delta \). Hence \( H \triangleleft \Delta \).

**Corollary 14.** A \( \Theta \)-regular hypermap \( \mathcal{H} \) is \( \Delta \)-regular if and only if for any orbit \( F_b^\Theta \), the function \( \Theta_{|_{F_b^\Theta}} \rightarrow \Theta_{|_{F_b^\Theta}}, x_{|_{F_b^\Theta}} \mapsto x_{|_{F_b^\Theta}} \) for \( i = 1, \ldots, m \), extends to an isomorphism.

**Corollary 15.** Let \( T = \{1 = b_1, \ldots, b_n\} \) be a transversal for \( \Theta \) in \( \Delta \). A \( \Theta \)-regular hypermap \( \mathcal{H} \) is \( \Delta \)-regular if and only if the \( \Theta \)-hypermaps \( \mathcal{H}_{b_1}, \ldots, \mathcal{H}_{b_n} \) are all isomorphic (that is, if and only if \( \mathcal{H} \) is isomorphic to all its \( b \)-images).

More generally, replacing \( \Delta \) by a normal subgroup \( \Pi \) of \( \Delta \) we get the following more general result:

**Corollary 16.** If \( \Theta \triangleleft \Pi \triangleleft \Delta \) (with both \( \Theta \triangleleft \Delta \) and \( \Pi \triangleleft \Delta \)) and \( T^n = \{1 = b_1, \ldots, b_n\} \) is a transversal for \( \Theta \) in \( \Pi \), then a \( \Theta \)-regular hypermap is \( \Pi \)-regular if and only if the \( \Theta \)-hypermaps \( \mathcal{H}_{b_1}, \ldots, \mathcal{H}_{b_n} \) are all isomorphic.

Although the \( \Theta \)-orbits of a \( \Theta \)-conservative hypermap \( \mathcal{H} \) all have the same length, the action of \( \Theta \) on them may not all be equivalent. Even if \( \mathcal{H} \) is \( \Theta \)-regular this may not be sufficient for \( \Theta \) acting equivalently on all \( \Theta \)-orbits. Let \( \mathcal{H} \) be \( \Theta \)-regular. For each \( b \in T \), the bijective function
\( \varphi_b : F^e_b \longrightarrow F^e_b, Ht \mapsto Htb, \) induces a commutative diagram

\[
\begin{array}{ccc}
F^e_b \times \Theta & \longrightarrow & F^e_b \\
\downarrow \varphi_b & & \downarrow \varphi_b \\
F^e_b \times \Theta & \longrightarrow & F^e_b
\end{array}
\]

if and only if \( \mathcal{H}^e \) is isomorphic to its \( b \)-image \( \mathcal{H}^e_b \). By Corollary 15, \( \Theta \) acts equivalently on all orbits if and only if \( \mathcal{H} \) is \( \Delta \)-regular. This proves:

**Theorem 17.** Let \( \mathcal{H} \) be a \( \Theta \)-regular hypermap. The action of \( \Theta \) on the \( \Theta \)-orbits are all equivalent if and only if \( \mathcal{H} \) is \( \Delta \)-regular.

Let \( b \) be an element of a transversal \( T \) for \( \Theta \) in \( \Delta \). Being \( \Theta \) normal in \( \Delta \), the \( \Theta \)-orbit \( F^e_b \) = \{Hbt \mid t \in \Theta \} \) can be written as the set \( \Theta \cdot H \cdot b = \{Htb \mid t \in \Theta \} \). The conjugate \( H^b \) is a subgroup of \( \Theta \) and the set of right cosets \( \Theta \cdot H^b = (\Theta \cdot H)^b \) is equipotent to the set of right cosets \( \Theta \cdot H \), which is equipotent to \( \Theta \cdot H \cdot b = F^e_b \). Hence the function

\[ Hbt \mapsto H^b t \]

is a bijection from \( F^e_b \) to \( \Theta \cdot H^b \). Moreover, the right action \( Hbt \cdot \tau \vert_{F^e_b} := Hbt \tau \) of \( \text{Mon}(\mathcal{H}^e_b) \) on \( F^e_b \) is equivalent to the right action

\[ H^b t \cdot H^b \tau = H^b t \tau \] of \( \Theta \cdot H^b \) on \( \Theta \cdot H^b \). Hence the \( b \)-image \( \mathcal{H}^e_b = (F^e_b ; x_1 \vert_{F^e_b} , \ldots , x_m \vert_{F^e_b}) \) is isomorphic to the \( \Theta \)-marked hypermap

\[ Q(H^b) = (\Theta \cdot H^b ; H^b x_1 , \ldots , H^b x_m) \]

with \( \Theta \)-marked fundamental subgroup \( H^b \).

Reciprocally, if \( Q = (\Omega ; \alpha_1 , \ldots , \alpha_m) \) is a \( \Theta \)-marked hypermap, as seen earlier \( Q \) is isomorphic to \( (\Theta \cdot Q ; Q_\alpha x_1 , \ldots , Q_\alpha x_m) \) for some \( \Theta \)-marked fundamental subgroup \( Q < \Theta \). Let \( \mathcal{H} \) be the hypermap \( (\Delta \cdot Q ; R_0 , Q_\alpha R_1 , Q_\alpha R_2) \), called here the \( \Delta \)-form of \( Q \). Then \( \mathcal{H} \) is \( \Theta \)-conservative and

\[ \mathcal{H}^e \cong (\Theta \cdot Q ; Q_\alpha x_1 , \ldots , Q_\alpha x_m) \cong Q. \]

**Lemma 18.** Let \( Q \) and \( K \) be subgroups of \( \Theta \) and let \( g \in \Theta \). Then \( \gamma_g : \Theta \cdot Q \longrightarrow \Theta \cdot K, Q t \mapsto K gt, \) is well defined if and only if \( Q \subset K^g \).

**Theorem 19.** Let \( Q = (\Theta \cdot Q ; Q_\alpha x_1 , \ldots , Q_\alpha x_m) \) and \( K = (\Theta \cdot K ; K_\alpha x_1 , \ldots , K_\alpha x_m) \) be two \( \Theta \)-marked hypermaps. Then \( Q \) covers \( K \) if and only if \( Q < K^g \) for some \( g \in \Theta \).
Proof. ($\Rightarrow$): If $\psi : \Theta/Q \rightarrow \Theta/K$ is a function commuting the respective actions, then $Q\psi = Kg$, for some $g \in \Theta$. Then, for all $t \in \Theta$, $Qt\psi = Q\psi t = Q\psi K_t = Kgt$, that is, $\psi = \gamma_g$. By Lemma 18, $Q < K^g$.

($\Leftarrow$): Reciprocally, if $Q < K^g$, for some $g \in \Theta$, then $\gamma_g$, as defined by Lemma 18 is well defined and determines a covering $Q \rightarrow K$. In fact, $Q < K^g$ implies that $Q_\Theta < K_\Theta$, then for all $t \in \Theta$ and $x \in \{x_1, \ldots, x_n\}$, $QtQ_\Theta x\gamma_g = Qtx\gamma_g = Kgtx = KgtK_\Theta x = Qt\gamma_g K_\Theta x$. Hence $\gamma_g$ commutes with both actions.

Let $Q = (\Theta/Q; Q_\Theta x_1, \ldots, Q_\Theta x_m)$ be a $\Theta$-marked hypermap with $\Theta$-marked fundamental subgroup $Q$. As seen above, $Q \cong H^\Theta$, where $H = (\Delta/Q; Q_\Delta R_0, Q_\Delta R_1, Q_\Delta R_2)$ is its $\Delta$-form, a $\Theta$-conservative hypermap with fundamental subgroup $Q$. Hence $Q$ is regular if and only if its $\Delta$-form $H$ is $\Theta$-regular. If the $\Theta$-marked fundamental subgroup $Q$ is normal in $\Delta$, we say that $Q$ is $\Delta$-symmetric. More generally, if $Q$ is normal in some normal subgroup $\Pi$ in $\Delta$, we say that $Q$ is $\Pi$-symmetric. So a $\Theta$-marked hypermap is $\Delta$-symmetric if and only if it has a regular $\Delta$-form hypermap.

Let us consider the two following $\Theta$-marked hypermaps:

$$Q_b = (\Theta/Q^b; Q_\Theta^b x_1, \ldots, Q_\Theta^b x_m)$$ (the $b$-image of $Q$)

and

$$Q^b = (\Theta/Q; Q_\Theta x_1^{b^{-1}}, \ldots, Q_\Theta x_m^{b^{-1}}).$$

**Theorem 20.** $Q_b \cong Q^b$.

**Proof.** The function $\psi_b : \Theta/Q^b \rightarrow \Theta/Q = \Theta^{b^{-1}}/Q$ defined by $Q^b t \mapsto Qt^{b^{-1}}$ is bijective and for all $t \in \Theta$ and $i \in \{1, \ldots, m\}$ it satisfies

$$Q^b tQ_\Theta x_i \psi_b = Q^b tx_i \psi_b = Q(t x_i)^{b^{-1}} = Qt^{b^{-1}} x_i^{b^{-1}} = Q^b t\psi_b Q_\Theta x_i^{b^{-1}}.$$

**Corollary 21.** Let $Q$ be a regular $\Theta$-marked hypermap. Then $Q$ is $\Delta$-symmetric if and only if $Q \cong Q^b$, $\forall b \in T$.

The last theorem of this section will be of great help in the construction of regular $\Theta$-marked hypermaps from given groups.

**Theorem 22.** If $G$ is a group generated by $g_1, \ldots, g_m$ such that the function $\rho : x_i \mapsto g_i$ extends to an epimorphism from $\Theta$ to $G$, then $Q = (G; g_1, \ldots, g_m)$ is a regular $\Theta$-marked hypermap.
Proof. As \( G \) acts transitively on itself by right multiplication then \( Q \) is a \( \Theta \)-marked hypermap. Moreover, the stabiliser of any element of \( G \) is trivial. Let \( Q = \text{Ker}(\rho) = \rho^{-1}(1) = \text{Stab}_\Theta(1) \) under the action of \( \Theta \) on \( G \) via \( \rho \). Then \( Q \triangleleft \Theta, G \cong \Theta/Q \) and \( Q \cong (\Theta/Q; Qx_1, \ldots, Qx_m) \). Hence \( Q \) is regular.

6. \( \Theta \)-slices

Any hypermap can be topologically constructed by stitching triangular pieces of surface, called flags, following the rule dictated by the monodromy group \([4, 17, 19, 20]\). If the hypermap is orientable, one can use the orientability to reduce the number of surface’s pieces by taking larger pieces, called darts, constructed by gluing two adjacent flags along their side labelled 2 (see Fig. 3). This approach can be brought to any \( \Theta \)-marked hypermap. The resulting building blocks will be called \( \Theta \)-slices. The “shape” of such a region is not unique, but differs according to the Schreier transversal considered for \( \Theta \).

Let \( T = \{b_1, \ldots, b_n\} \) be a Schreier transversal for \( \Theta \) in \( \Delta \). Associated with \( T \) we construct a \( \Theta \)-slice, in fact a rooted \( \Theta \)-slice, in the following way. Fix a flag \( \omega \), a topological triangle similar to the one displayed in Fig. 1 (left), with their three sides labelled 0, 1, 2 and their corresponding opposite vertices labelled similarly. The side labelled 2, lying on the underlying hypergraph, will be drawn thick while the other two (lying inside of hyperfaces) will be dashed. To get some geometrical meaning we do this on the hyperbolic plane \( \mathbb{H} \), modelled by the Poincaré disc. Here a flag is a hyperbolic triangle with internal zero angles. Let \( R_0, R_1 \) and \( R_2 \) be the usual reflections on the sides labelled 0, 1 and 2 respectively. They generate a group isomorphic to the “triangle” group \( \Delta \). Each element \( b_i \in T \) is a word in \( R_0, R_1, R_2 \), so \( \omega b_i \) is an isometric flag in \( \mathbb{H} \). The region \( \zeta_\omega = \cup \{\omega b \mid b \in T\} \), which is connected since \( T \) is a Schreier transversal, is our starting rooted \( \Theta \)-slice (associate to \( T \)) with root flag \( \omega \). Fig. 1 (right) displays a rooted \( \Theta \)-slice, where \( \Theta \) is the subgroup \( \Delta^{\delta_i} = \langle R_2, (R_0 R_1)^2 \rangle^\Delta \) of \( \Delta \).

![Figure 1: Left: a flag. Right: A rooted \( \Delta^{\delta_i} \)-slice, consisting of 4 flags.](image-url)
The set of root \( \Theta \)-flags is \( S_\omega = \{ \omega t \mid t \in \Theta \} \) with root-flags \( \omega t, t \in \Theta \).
The group \( \Theta \) acts regularly on \( S_\omega \) by acting on the root-flags \( \omega t \), giving rise to a \( \Theta \)-tessellation \( T \) of \( \mathbb{H} \) by rooted \( \Theta \)-slices (Fig. 2).

![Figure 2: Part of the \( \Delta^{0i} \)-tessellation in \( \mathbb{H} \).]

One can choose any other flag \( \omega' = \omega b \) \((b \in T)\) of \( \zeta_\omega \) to be a (starting) root-flag; in fact, \( T' = b^{-1}T \) is also a Schreier transversal for \( \Theta \) (see lemma below) and \( \zeta_{\omega'}^T = \zeta_\omega^T \), so \( \zeta_{\omega'}^T \) represents the same \( \Theta \)-slice with root-flag \( \omega' \) (yet associated to \( T' \)). Therefore, choosing another flag for root-flag is equivalent to associating the \( \Theta \)-slice with another Schreier transversal.

**Lemma 23.** If \( T = \{1 = b_1, \ldots, b_n\} \) is a Schreier transversal for \( \Theta \) in \( \Delta \), then for \( i = 1, \ldots, n \) the set \( b_i^{-1}T = \{b_i^{-1}b_1, \ldots, b_i^{-1}b_n\} \) is still a Schreier transversal for \( \Theta \) in \( \Delta \).

**Proof.** The function \( \epsilon_i : b_i^{-1}T \to T, x \mapsto b_ix \), is a bijection. Hence \( |b_i^{-1}T| = |T| \). On the other hand, for all \( b, b' \in T \), \( \Theta b_i^{-1}b = \Theta b_i^{-1}b' \iff b_i^{-1}\Theta b = b_i^{-1}\Theta b' \iff \Theta b = \Theta b' \iff b = b' \iff b_i^{-1}b = b_i^{-1}b' \). Hence \( b_i^{-1}T \) is a transversal and contains 1. Let \( w \in b_i^{-1}T \) such that \( w = w' \). Then \( b_iw = b_iuv \in T \), and since \( T \) has the Schreier property, \( b_iu \in T \iff u \in b_i^{-1}T \). Hence \( b_i^{-1}T \) is also a Schreier transversal. \( \square \)

Each \( \Theta \)-slice \( \zeta = \cup \{ \omega b \mid b \in T \} \) in \( \mathcal{H} \) is a union of \( n \) (the index of \( \Theta \) in \( \Delta \)) flags, each belonging to a different \( \Theta \)-orbit. This gives rise to \( n \) coloured flags in \( \zeta \), inducing \( n \) colourings (or roots) to the \( \Theta \)-slices. Choosing a root colour (or root-flag \( \omega \)) then the action of \( \Theta \) on the coloured-flags will fix a root-flag in each \( \Theta \)-slice giving rise to a set of \( n \) coloured rooted \( \Theta \)-slices \( S_\omega \). Figure 3 shows \( \Theta \)-slices for some familiar subgroups \( \Theta \) in \( \Delta \) with abelian factors, namely, \( \Theta = \Delta, \Theta = \Delta^+, \Theta = \Delta^\circ = \langle R_1, R_2 \rangle \) and \( \Delta^{012} = \langle R_0 R_1 R_2 \rangle \).
Figure 3: $\Delta$-slice (or flag), $\Delta^+$-slice (or dart), $\Delta^0$-slice and $\Delta^{012}$-slice.

Of course different subgroups $\Theta$ of finite index in $\Delta$ may share the
same $\Theta$-slice when taking appropriate Schreier transversals. For exam-
ple, $\Delta^0 = \langle R_0, R_1R_2 \rangle^\Delta$, of index 2, may also induce the same $\Delta^+$-slice,
$\Theta = \Delta^{02} = \langle R_1, (R_2R_0)^2 \rangle^\Delta$, $\Delta^{+0} = \Delta^+ \cap \Delta^0$ and $\Delta^{+2} = \Delta^+ \cap \Delta^2$, all of
index 4, may also induce the same $\Delta^{012}$-slice. For more details on these
and the regular hypermaps associated to them see [5].

Let $Q$ be a $\Theta$-marked hypermap with $\Theta$-marked fundamental sub-
group $Q$. Being $Q$ a subgroup of $\Theta$, $Q$ also acts on the rooted $\Theta$-slices.
This determines a fundamental region $R \subset \mathbb{H}$, which can be seen as
a regular hyperbolic polygon divided into rooted $\Theta$-slices. The orbit
space $\mathbb{H}/Q$, which corresponds to the polygon $R$ with their sides pair-
wise identified, carries a $\Theta$-conservative hypermap $\mathcal{H}$ (also divided into
rooted $\Theta$-slices) as an imbedding of the hypergraph determined by the
thick lines of the induced tessellation $T$ on $R$. The induced (topological)
$\Theta$-conservative hypermap $\mathcal{H}$ is clearly isomorphic to $Q$ (in respect to the
induced root flags). The choice of another root flag in $\mathcal{H}$ determines a
$b$-image of $Q$. When $Q$ is $\Delta$-symmetric (i.e., its $\Delta$-form is regular), then
the choice of a root flag in $\mathcal{H}$ becomes irrelevant. In this case we may
discard the root flags and consider $\Theta$-slices instead of rooted $\Theta$-slices.

7. An example

Consider the subgroup $\Delta^{01} = \langle R_2, R_2R_0, R_2R_1, R_2R_0R_1, (R_0R_1)^2 \rangle$ with
index 4 in $\Delta$. This is one of the seven normal subgroups with index
4 in $\Delta$ [6]. It is isomorphic to a free product $C_2 * C_2 * C_2 * C_2 *$
$C_\infty = \langle A, B, C, D, Z \rangle$. Associated to the Schreier transversal $T =$
$\{1, R_0, R_1, R_0R_1 \}$ for $\Delta^{01}$ in $\Delta$, we have the rooted $\Delta^{01}$-slice shown
in Fig. 1 (right).

Let us consider the Klein four group $V_4$ and let $Q$ be the regular
$\Delta^{01}$-marked hypermap $(V_4, a, b, c, d, z)$, where $V_4 = \langle a, b \rangle$, $c = ab$ and
d = z = b. To construct $Q$ as a cellular embedding of a hypergraph in
some surface $S$, take 4 rooted $\Delta^{01}$-slices numerated as 1, 2, 3 and 4.
Since $1a$, $1ab$ and $1aba$ are different $\Delta^{01}$-slices, without loss of generality, assign $2 = 1a$, $3 = 2b$ and $4 = 3a$. Since $c = (r_0r_2)^2$ is an involution, we must have these slices joined partially as shown in Fig. 5.

Now the equation $c = ab$ applied to the root flags implies $A5 = A13$ and $A6 = A14$. The equation $z = b$ on the root flags is equivalent to $r_{1}^{r_{0}} = r_{2}^{r_{0}}r_{1}$ on root flags, and this implies $A3 = A15$, $A8 = A12$, $A16 = A4$ and $A11 = A7$. Similarly, $d = z$ on the root flags is equivalent to $r_{1}r_{0} = r_{0}r_{1}r_{2}$ and this implies $A1 = A2$ and $A9 = A10$. The final picture is shown in Fig. 6.

The $\Delta$-form of $Q$ is $\Delta^{01}$-regular.
8. Θ-regularity as a regular covering

The trivial Θ-hypermap $\mathcal{T}_\Theta$, that is, the regular hypermap with fundamental subgroup $\Theta$, is the smallest Θ-conservative hypermap. Its flag’s set is the quotient $\Delta/\Theta$ and hence the number of flags of $\mathcal{T}_\Theta$ is the index of $\Theta$ in $\Delta$. If a hypermap $\mathcal{H}$ is Θ-conservative, its fundamental subgroup $H$ is a subgroup of $\Theta$ and so we have a covering $\rho : \mathcal{H} \rightarrow \mathcal{T}_\Theta$ given by $\rho : \Delta/H \rightarrow \Delta/\Theta$, $Hd \mapsto \Theta d$. The size of $\mathcal{T}_\Theta$ can be seen as the number of Θ-orbits in $\mathcal{H}$. The covering $\rho$ is regular if $H < \Theta$, that is, if $\mathcal{H}$ is Θ-regular, in which case the covering group is given by $\Theta/H$.

Let $T = \{b_1 = 1, b_2, \ldots, b_n\}$ be a transversal for $\Theta$ in $\Delta$. Being Θ-conservative then each Θ-orbit $F_{b_i}^{\Theta} = \{Hb_it \mid t \in \Theta\}$ in $\mathcal{H}$ is a “fiber” $(\Theta b_i)\rho^{-1}$; in fact,

$$(\Theta b_i)\rho^{-1} = \{Hd \in \Delta/H \mid \Theta d = \Theta b_i\}$$

$$= \{Htb_i \in \Delta/H \mid t \in \Theta\}$$

$$= \{Hb_ip \in \Delta/H \mid t' = b_i^{-1}tb_i = t^{b_i} \in \Theta\}$$

$$= F_{b_i}^{\Theta}.$$  

The function $\phi : (\Theta \rho^{-1}) \rightarrow \Theta \rho^{-1} = \Theta/H, Hg \mapsto Hgd^{-1}$, is a bijection from any fiber $(\Theta d)\rho^{-1}$ to the “main” fiber $\Theta \rho^{-1} = \Theta/H$. This confirms an earlier result saying that any two Θ-orbits have the same length.

9. Θ-type and characteristic of a Θ-regular hypermap

Let $\mathcal{H}$ be a Θ-regular hypermap. The Θ-automorphism group $\text{Aut}^\Theta(\mathcal{H})$ acts regularly on any Θ-orbit. For each hypervertex $v$ of $\mathcal{H}$, denote by $F_v$ the set of flags incident with $v$. The “Θ-stabiliser”

$$E_{F_v}^{\Theta} = \text{Stab}_{\text{Aut}^\Theta(\mathcal{H})} (F_v)$$

is a subgroup of $\langle r_1, r_2 \rangle \subset \text{Aut}^\Theta(\mathcal{H})$ (which is cyclic or dihedral). Since $E_{F_v}^{\Theta}$ is a subgroup of $\text{Aut}^\Theta(\mathcal{H})$ it acts regularly on the subset of flags $\omega\Theta \cap F_v$ of each Θ-orbit $\omega\Theta$ meeting $v$. Then $|\omega\Theta \cap F_v| = |E_{F_v}^{\Theta}|$ and hence part (1) of the next theorem is established. Since automorphisms preserve incidence, any automorphism $\psi$ can be seen as a function that sends i-hypercells (0-hypercells=hypervertices, 1-hypercells=hyperedges and 2-hypercells=hyperfaces) to i-hypercells. Moreover, incidence shows
that for any hypercell \( c \), \( F_c \psi = F_c \psi \). So if \( \varphi \) is a \( \Theta \)-automorphism then for any flag \( \omega \), \( \omega \Theta \varphi = \omega \Theta \) and so, for any hypervertex \( v \),

\[
(\omega \Theta \cap F_v) \varphi = \omega \Theta \cap F_v \psi.
\]

This helps to finish the proof of the following theorem.

**Theorem 24.** Let \( \mathcal{H} \) be a \( \Theta \)-regular hypermap.

1. If two \( \Theta \)-orbits meet in one hypervertex \( v \) (resp. hyperedge, hyperface), then they both meet \( v \) with \( |E^\Theta_{F_v}| \) flags.
2. Let \( \omega \Theta \) be a \( \Theta \)-orbit meeting two different vertices \( u \) and \( v \). If \( \omega \Theta \) meets \( u \) with \( k \) flags, then \( \omega \Theta \) also meets \( v \) with \( k \) flags.
3. If two \( \Theta \)-orbits meet in one hypervertex (resp. hyperedge, hyperface), then they will meet at exactly the same hypervertices (resp. hyperedges, hyperfaces).

**Proof.** (2) The transitivity of \( \text{Aut}^\Theta(\mathcal{H}) \) on \( \Theta \)-orbits implies that there is \( \phi \in \text{Aut}^\Theta(\mathcal{H}) \) such that \( u \phi = v \). Then \( (\omega \Theta \cap F_u) \phi = \omega \Theta \cap F_v \) and so \( |\omega \Theta \cap F_v| = |\omega \Theta \cap F_u| = k \).

(3) Let \( \omega_1 \Theta, \omega_2 \Theta \) be two \( \Theta \)-orbits meeting the hypervertex \( u \). Without loss of generality we may suppose that \( \omega_1, \omega_2 \in F_u \). If \( \omega_1 \Theta \) meets another hypervertex \( v \), then the transitivity of \( \text{Aut}^\Theta(\mathcal{H}) \) on \( \Theta \)-orbits implies that there is \( \phi \in \text{Aut}^\Theta(\mathcal{H}) \) such that \( u \phi = v \). Then \( (\omega_2 \Theta \cap F_u) \phi = \omega_2 \Theta \cap F_v \neq \emptyset \), that is, \( \omega_2 \Theta \) also meets \( v \).

Two distinct \( \Theta \)-orbits may meet different numbers of hypervertices (resp. hyperedges, hyperfaces). However, in a \( \Theta \)-regular hypermap \( \Theta \)-orbits lie inside \( \text{Aut}(\mathcal{H}) \)-orbits, and so, if two distinct \( \Theta \)-orbits lie inside the same \( \text{Aut}(\mathcal{H}) \)-orbit then the following result says that despite they may not meet the same hypervertices they will meet the same number of hypervertices.

**Theorem 25.** Let \( \mathcal{H} \) be a \( \Theta \)-regular hypermap and \( \omega_1, \omega_2 \) be two flags in the same \( \text{Aut}(\mathcal{H}) \)-orbit. Then the \( \Theta \)-orbits \( \omega_1 \Theta \) and \( \omega_2 \Theta \) meet the same number of hypervertices (resp. hyperedges, hyperfaces) with the same number of flags.

**Proof.** This is a consequence of \( \omega_1 \Theta \psi = \omega_1 \psi \Theta \), for any automorphism \( \psi \in \text{Aut}(\mathcal{H}) \). In fact, since \( \omega_1 \) and \( \omega_2 \) belong to an \( \text{Aut}(\mathcal{H}) \)-orbit, there is \( \psi \in \text{Aut}(\mathcal{H}) \) such that \( \omega_2 = \omega_1 \psi \). If \( \omega_1 \Theta \) meets the \( k \) hypervertices \( v_1, \ldots, v_k \), so \( v_1, \ldots, v_k \) are all the hypervertices such that \( \omega_1 \Theta \cap F_{v_i} \neq \emptyset \), for any \( i = 1, \ldots, k \), then also \( (\omega_1 \Theta \cap F_{v_i}) \psi = \omega_2 \Theta \cap F_{u_i} \psi \neq \emptyset \). Since \( \psi \) is invertible, \( u_1 \psi, \ldots, u_k \psi \) are all the hypervertices that \( \omega_2 \Theta \) meets. By
Part (2) of Theorem 24, the sets $\omega_1 \mathcal{H} \cap F_{\omega_i}$, $i = 1, \ldots, k$, all have the same cardinality, thus so do the sets $\omega_2 \mathcal{H} \cap F_{\omega_i}$ for $i = 1, \ldots, k$. \qed

Consider the regular covering $\rho : \mathcal{H} \longrightarrow T_\Theta$. As we saw in §8, each $\Theta$-orbit is a fiber $(\Theta b_i)\rho^{-1}$. Let $v$ be a hypervertex of $T_\Theta$ and $w$ a flag in $v$. The valency of $v$ divides the valency of each hypervertex $v_i \in \{v\}\rho^{-1}$ in $\mathcal{H}$ that projects over $v$. The $\Theta$-orbit $\{w\}\rho^{-1}$ meets every hypervertex of $\{v\}\rho^{-1}$, hence, by Theorem 24, all the hypervertices in $\{v\}\rho^{-1}$ share the same valency. Similarly, all the hyperedges (resp. hyperfaces) in $\mathcal{H}$ that cover an hyperedge (resp. hyperface) of $T_\Theta$ share the same valency.

Let $\{v_1, \ldots, v_{q_v}\}, \{e_1, \ldots, e_{q_e}\}$ and $\{f_1, \ldots, f_{q_f}\}$ be the hypervertices, hyperedges and hyperfaces (respectively) of the trivial $\Theta$-hypermap $T_\Theta$ and $(k; l; m)$ be the type of $T_\Theta$; so $q_v$, $q_e$ and $q_f$ are the number of hypervertices, hyperedges and hyperfaces of $T_\Theta$, respectively. Let $\mathcal{V}_i = \{v_i\}\rho^{-1}$, $\mathcal{E}_i = \{e_i\}\rho^{-1}$ and $\mathcal{F}_i = \{f_i\}\rho^{-1}$ be the sets of hypervertices, hyperedges and hyperfaces of $\mathcal{H}$ projecting via $\rho$ to $v_i$, $e_i$ and $f_i$ respectively. These have common valencies respectively $k_i$, $l_i$ and $m_i$. Notice that $k$ divides each $k_i$ ($i = 1, \ldots, q_v$), $l$ divides each $l_i$ ($i = 1, \ldots, q_e$) and $m$ divides each $m_i$ ($i = 1, \ldots, q_f$). The following sequence

$$(k_1, \ldots, k_{q_v}; l_1, \ldots, l_{q_e}; m_1, \ldots, m_{q_f})$$

will be called the $\Theta$-type of $\mathcal{H}$. The $q_v$ hypervertices (resp. $q_e$ hyperedges and $q_f$ hyperfaces) of $T_\Theta$ give rise to $q_v$ 0-colours (or vertex-colours) among the hypervertices of $\mathcal{H}$ (resp. $q_e$ 1-colours and $q_f$ 2-colours). The underlying hypergraph $\mathcal{G}$ of $\mathcal{H}$ is then $(q_v, q_e)$-coloured"#, that is, as a bipartite graph it is a $(q_v + q_e)$-vertex coloured graph.

9.1. Characteristic of a $\Theta$-regular hypermap without boundary

Denote by $\mathcal{V} = \bigcup_{i=1}^{q_v} \mathcal{V}_i$, $\mathcal{E} = \bigcup_{i=1}^{q_e} \mathcal{E}_i$ and $\mathcal{F} = \bigcup_{i=1}^{q_f} \mathcal{F}_i$ the sets of hypervertices, hyperedges and hyperfaces of $\mathcal{H}$. Then $\sum_{i=1}^{q_v} |\mathcal{V}_i| = |\mathcal{V}|$, $\sum_{i=1}^{q_e} |\mathcal{E}_i| = |\mathcal{E}|$ and $\sum_{i=1}^{q_f} |\mathcal{F}_i| = |\mathcal{F}|$. As all the hypervertices in $\mathcal{V}_i$ have the same valency $k_i$, and $\mathcal{H}$ has no boundary, then we have $2k_i|\mathcal{V}_i|$ flags lying on $\mathcal{V}_i$. On the other hand, the hypervertices of $\mathcal{V}_i$ project over $v_i$ and around $v_i$ we have $\mu_v k$ flags, where $\mu_v = 1$ if $v$ is on the boundary of $T_\Theta$ and $\mu_v = 2$ if not. Then the number of flags lying around the vertices of $\mathcal{V}_i$ must also be given by $\mu_v k |\Theta : H|$; that is,

$$2k_i |\mathcal{V}_i| = \mu_v k |\Theta : H|.$$
Analogously we define the numbers $\mu_e$ for hyperedges and $\mu_f$ for hyperfaces, with similar formulas

\begin{align*}
2m_i |E_i| &= \mu_e v |H|, \\
2m_i |F_i| &= \mu_f m |H|.
\end{align*}

As $|F| = n |H|$ then the characteristic $\chi$ of $H$ is given by

\begin{align*}
\chi(H) &= |V| + |E| + |F| - \frac{|F|}{2} \\
&= \sum_{i=1}^{q_e} |V_i| + \sum_{i=1}^{q_e} |E_i| + \sum_{i=1}^{q_f} |F_i| - \frac{n |H|}{2} \\
&= \sum_{i=1}^{q_e} \frac{\mu_e k_i |H|}{2k_i} + \sum_{i=1}^{q_e} \frac{\mu_e l |H|}{2l_i} + \sum_{i=1}^{q_f} \frac{\mu_f m |H|}{2m_i} - \frac{n |H|}{2}.
\end{align*}

For $\Theta$-regular hypermaps of negative characteristic $N = -\chi > 0$, this formula permits the evaluation of an upper bounding for $|\text{Aut}^\Theta(H)| = |H| \cdot \text{factor}$ for each ordering of $\{k_1, \ldots, k_{q_e}, l_1, \ldots, l_{q_e}, m_1, \ldots, m_{q_f}\}$. Choosing the highest upper bounding on all possible orderings (the number of orderings is finite), we get the following kind of "Riemann-Hurwitz" bound:

**Theorem 26.** For each $N > 0$, there is $\Sigma_\Theta < \frac{n}{2}$ such that

\[ |\text{Aut}^\Theta(H)| \leq \frac{N}{\frac{n}{2} - \Sigma_\Theta} \]

for any $\Theta$-regular hypermap $H$.

For example, for $\Theta = \Delta$ the bound is $84N$, for $\Theta = \Delta^+$ the bound is $42N$ (the Hurwitz bound $84(g - 1)$ as it is known, where $g$ is the genus), for $\Theta = \Delta^0$ the bound is $24N$ and for $\Theta = \Delta^012$ the bound is $6N$. Since any $\Theta$-regular hypermap is fully determined by its $\Theta$-automorphism group we have,

**Corollary 27.** For each $\Theta$ and for each $N > 0$ the number of $\Theta$-regular hypermaps of negative characteristic $N$ is finite.

In other words, given a regular hypermap $T$, the number of hypermaps $H$ of given negative characteristic $N > 0$ that regularly covers $T$ is finite.

10. Restrictly regular hypermaps

We say that a hypermap $H$ is *restrictly regular* if $H$ is $\Theta$-regular for some normal subgroup $\Theta$ with finite index in $\Delta$. The *restricted rank* $r$
of a restrictly regular hypermap is the index \( r \) of the greatest normal subgroup \( \Theta \) in \( \Delta \) such that \( \mathcal{H} \) is \( \Theta \)-regular. Restricted rank 1 means that \( \mathcal{H} \) is \( \Delta \)-regular, or simply regular. Let the restricted co-rank of a hypermap \( \mathcal{H} \) to be the quotient \( |F|/r \); this is the \( \Theta \)-orbit's length of a \( \Theta \)-regular hypermap of restricted rank \( r = |\Delta : \Theta| \). As the length of a \( \Theta \)-orbit of a \( \Theta \)-regular hypermap \( \mathcal{H} \) must divide \( |\text{Aut}(\mathcal{H})| \), which is the length of an \( \text{Aut}(\mathcal{H}) \)-orbit, we have:

**Lemma 28.** The restricted co-rank of a restrictly regular hypermap \( \mathcal{H} \) must be a divisor of \( |\text{Aut}(\mathcal{H})| \).

For example, if \( \mathcal{H} \) is not regular and has trivial automorphism group then \( \mathcal{H} \) cannot be restrictly regular. In fact, if \( \mathcal{H} \) is \( \Theta \)-regular for some \( \Theta < \Delta \), since \( \text{Aut}^\Theta(\mathcal{H}) < \text{Aut}(\mathcal{H}) \) then \( |\Theta/H| = |F^\Theta| = |\text{Aut}^\Theta(\mathcal{H})| = 1 \), where \( H \) is the fundamental subgroup of \( \mathcal{H} \). So \( H = \Theta \) and \( \mathcal{H} \) is regular, which is against our assumption. Examples providing larger automorphism groups is given by the following theorem, where hyperfaces can be replaced by hypervertices or hyperedges.

**Theorem 29.** Let \( \mathcal{H} \) be a hypermap with a hyperface \( A \) of valency \( m \) and another \( B \) of valency \( n \). If \( m \) and \( n \) are coprimes, and the rotation one step about \( A \) or \( B \) is not an automorphism of \( \mathcal{H} \), then \( \mathcal{H} \) cannot be restrictly regular.

**Proof.** Since \( \mathcal{H} \) is not regular the automorphism group \( \text{Aut}(\mathcal{H}) \) acts with at least 2 orbits in the set of flags \( F \) of \( \mathcal{H} \). Suppose that \( \mathcal{H} \) is \( \Theta \)-regular for some normal subgroup \( \Theta \) of finite index in \( \Delta \). Let \( H \) be the fundamental subgroup of \( \mathcal{H} \) and let \( \beta = H \in F = \Delta/H \) be a flag in \( A \). Since \( \mathcal{H} \) is \( \Theta \)-conservative, \( H \subset \Theta \), and since \( \beta(r_0r_1)^m = \beta \), that is, \( HH_\Delta(r_0r_1)^m = H \), then \( (r_0r_1)^m \in H \), and so, \( (r_0r_1)^m \in \Theta \). If \( \gamma = Hd \in F \) is a flag in \( B \) then \( \gamma(r_0r_1)^n = \gamma \), which implies that \( (r_0r_1)^n \in Hd \subset \Theta \). Now \( \gcd(m,n) = 1 \), so there are integers \( p, q \) such that \( pm + qn = 1 \), and so, \( r_0r_1 = (r_0r_1)^p(r_0r_1)^q \in \Theta \). Now the \( \Theta \)-regularity of \( \mathcal{H} \) implies that \( \text{Aut}^\Theta(\mathcal{H}) \) acts regularly on both \( \Theta \)-orbits \( \beta \Theta \) and \( \gamma \Theta \). Since \( \Theta \) contains \( r_0r_1 \), this means that the rotations one step on both hyperfaces \( A \) and \( B \) are automorphisms of \( \mathcal{H} \), which is against our hypothesis. \( \square \)

**Corollary 30.** If \( \mathcal{M} \) is a regular map of type \( \{p, q\} \) with \( \gcd(2p, q) = 1 \), then the truncated map \( T\mathcal{M} \) is not restrictly regular.

**Proof.** \( T\mathcal{M} \) has two type of faces, the face-faces (faces originating from the original faces) of valency \( 2p \) and the vertex-faces (faces originating from the vertices) of valency \( q \). The rotation one step about a
face-face cannot be an automorphism of $T\mathcal{M}$ since it takes a face-face to a vertex-face with different valency.

It is therefore reasonable to ask when a given hypermap $\mathcal{H}$ is, or is not, restrictly regular. Let $\mathcal{H}$ be a hypermap with fundamental subgroup $H$. The normaliser $N_{\Delta}(H)$ gives rise to a not necessarily regular hypermap $\mathcal{N}$, call it the normaliser of $\mathcal{H}$. The hypermap $\mathcal{H}$ regularly covers $\mathcal{N}$, with covering transformation group $N_{\Delta}(H)/H \cong \text{Aut}(\mathcal{H})$. Denote by $\mathcal{H}$ the regular hypermap with fundamental subgroup $\Phi = (N_{\Delta}(H))_{\Delta}$. This group $\Phi$, which we will call the regularity-subgroup of $\mathcal{H}$, is the greatest normal subgroup $\Theta$ in $\Delta$ such that $\mathcal{H}$ has the possibility to be $\Theta$-regular. If $\mathcal{H}$ is regular, then $\Phi = \Delta$ and consequently $\Delta/\Phi$ is trivial. Note that $\Phi$ is a subgroup of $N_{\Delta}(H)$, so if $H < \Phi$ then $H \triangleleft \Phi$ and $\Phi/H = \text{Aut}(\mathcal{H}) < \text{Aut}(\mathcal{H})$.

**Theorem 31.** $\mathcal{H}$ is restrictly regular if and only if the regularity-subgroup contains the fundamental subgroup. Moreover, if $\mathcal{H}$ is restrictly regular then the regularity-subgroup $\Phi$ is the greatest normal subgroup $\Theta$ with finite index in $\Delta$ such that $\mathcal{H}$ is $\Theta$-regular, and hence, $\mathcal{H}$ has restricted rank $|\Delta : \Phi|$.

**Proof.** If $\mathcal{H}$ is $\Theta$-regular for some normal subgroup $\Theta$ (with finite index) in $\Delta$, then $H \subset \Theta \subset N_{\Delta}(H)$. As $\Theta \triangleleft \Delta$ then $\Theta \subset (N_{\Delta}(H))_{\Delta}$ and hence $H \subset (N_{\Delta}(H))_{\Delta}$.

Conversely if $H \subset (N_{\Delta}(H))_{\Delta}$, since $H \triangleleft N_{\Delta}(H)$ and $(N_{\Delta}(H))_{\Delta} < N_{\Delta}(H)$, then $H \triangleleft (N_{\Delta}(H))_{\Delta}$ and $\mathcal{H}$ is $\Theta$-regular for $\Theta = (N_{\Delta}(H))_{\Delta}$, which is a normal subgroup of $\Delta$ with finite index.

Not every hypermap is restrictly regular, in other words, not every hypermap regularly covers a regular hypermap. As mentioned earlier, if $\mathcal{H}$ has trivial automorphism group then $N_{\Delta}(H) = H$ and so, $\Phi = (N_{\Delta}(H))_{\Delta} = H_{\Delta}$. If $H \neq \Delta$, then $H$ strictly contains $H_{\Delta}$ and $\mathcal{H}$ is not restrictly regular.

Of the 14 automorphism types of edge-transitive maps classified by Graver and Watkins [15], see also [27], 11 correspond to restrictly regular maps, namely: type 1 corresponds to $\Delta$-regularity; types 2, 2*, 2p, 2ex, 2*ex and 2p correspond to $\Delta^{0}$, $\Delta^{2}$, $\Delta^{1}$, $\Delta^{2}$, $\Delta^{0}$, and $\Delta^{+}$-regularity of restricted rank 2; type 3 corresponds to $\Delta^{02}$-regularity of restricted rank 4; types 5, 5* and 5p correspond to $\Delta^{+0}$, $\Delta^{+2}$, and $\Delta^{012}$-regularity of restricted rank 4.
The Buckminsterfullerene (or buckyball), the prototypical member $C_{60}$ of a family of highly symmetrical carbon-cage molecules whose discovery has led to the 1996 Nobel Prize in Chemistry, can be modelled as a truncated Icosahedron. As the Icosahedron is a regular map of type \{3,5\} and gcd(3,10) = 1, Theorem 30 says that the buckyball is not restrictively regular. This apparent contradiction to its highly symmetrical shape has an explanation. We have been representing a hypermap as a bipartite map. However, traditionally a hypermap \( \mathcal{H} \) has been defined as a cellular imbedding of a 3-valent graph \( \mathcal{G} \) whose faces can be 3-coloured in such a way that they all meet at each vertex. The vertices of \( \mathcal{G} \) is the set of flags and the 3 coloured faces make up the hypervertices, hyperedges and the hyperfaces of \( \mathcal{H} \). The bipartite map representation arises when the 0- and 1- faces (the coloured faces that represent the hypervertices and hyperedges, respectively) shrink to points, the vertices of the bipartite map. If \( \mathcal{H} \) is a map, we can shrink the 1-faces, “rectangles” like faces, to edges. The buckyball, or the truncated icosahedron, seen in this way represents the map Icosahedron as an imbedding of a 3-valent graph whose 1-faces were shrinked to edges. In this view, the buckyball is a regular hypermap.

The cellular graph imbedding (or map) appearing in Picture 10 of page 405 of Burnside monograph [11], is clearly not regular, but, unlike the buckyball, it is restrictively regular. Redrawing the map in the Riemann sphere, or inserting \( \infty \) to form a 1-compactification of the plane, the Burnside’s map becomes the picture shown in Figure 7(a).

![Figure 7: A sphere with n (even) sections with an equatorial rim.](image)

Burnside considered only the darker regions to represent a dihedral group \( D_{n/2} \). Let us assume \( n \) either even or odd and let \( \mathcal{M} \) be the map. The automorphism group of \( \mathcal{M} \) is a direct product \( D_n \times C_2 \) that acts with 3 orbits, the white, dark and grey flags (Fig. 7(b)). Hence the restricted rank \( r \) shall be greater than 3. If \( n \) is odd, we have two vertices whose valency are coprime. Since the rotation one step about
an equatorial vertex is not an automorphism of \( \mathcal{M} \), by Theorem 29, \( \mathcal{M} \) is not strictly regular. If \( n \) is even, let us show that \( \mathcal{M} \) is strictly regular with restricted rank 6. The number of flags is 12n and each \( \text{Aut}(\mathcal{M}) \)-orbit has \( 4n = |\text{Aut}(\mathcal{M})| \) flags. By lemma 28, the restricted co-rank \( s \) must divide properly \( 4n \), i.e., \( s \neq 4n \); the highest possible value is obtained when \( s = 2n \), giving a possible value of 6 for its rank \( r \). The normal closure \( \Theta = \langle R_2, (R_0 R_1)^3 \rangle^\Delta \) has index 6 in \( \Delta \) and since \( R_2, R_2^{R_0}, (R_0 R_2)^2 = R_2^{R_0} R_2, R_2^{R_1}, (R_1 R_2)^2 = R_2^{R_1} R_2, (R_1 R_2)^4 \in \Theta \), it is not difficult to see that \( \mathcal{M} \) is \( \Theta \)-conservative. As a \( \Theta \)-orbit lies inside an \( \text{Aut}(\mathcal{M}) \)-orbit (Fig. 7(c)), \( \text{Aut}^\Theta(\mathcal{M}) \) acts transitively on a \( \Theta \)-orbit, so \( \mathcal{M} \) is \( \Theta \)-regular. Hence \( \mathcal{M} \) is restrictly regular with restricted rank 6. Note that by Riedmeister-Schreier’s Rewriting Process, \( \Theta = \langle A, B, C, D, E, F, Z \rangle \cong C_2 \star C_2 \star C_2 \star C_2 \star C_2 \star C_\infty \), where \( A = R_2, B = R_2^{R_0}, C = R_2^{R_0 R_1}, D = R_2^{R_0 R_1 R_0}, E = R_2^{R_1}, F = R_2^{R_1 R_2} \) and \( Z = (R_0 R_1)^3 \). The regular \( \Theta \)-marked map induced by \( \mathcal{H} \) is \( Q = (D_2 \times C_2; a, a, c, d, c, c, 1) \), where \( D_2 = \langle c, d \mid c^2 = d^2 = (cd)^{\frac{3}{2}} = 1 \rangle \) and \( C_2 = \langle a \rangle \).

Meanwhile, we may see the dark and white regions as dark and white flags. In this way Fig. 7(a) is a regular map on the sphere with two vertices (the poles), without the equatorial rim. Burnside’s view correspond to the oriented version of this, a regular oriented map with dihedral automorphism group.
