Abstract: Coenzyme Q\textsubscript{10} (CoQ\textsubscript{10}), a vitamin E-like substance, represents a components of the complex antioxidant system of the human organism. CoQ\textsubscript{10} levels in human plasma were determined by high performance liquid chromatography (HPLC) with UV detection. It was dissociated from lipoproteins by methanol and extracted into n-hexane with liquid-liquid extraction procedure, after centrifugation, the supernatant was dried under nitrogen gas stream. The residue was dissolved in the absolute ethanol. Determination of CoQ\textsubscript{10} was performed on a C18 reversed-phase analytical column with ultraviolet detection at 275 nm and the mobile phase containing 15% (v/v) ethanol in methanol at a flow rate of 1.7 mL/min. The low limit of quantitation was 0.02 mg/L.

Analysis of coenzyme Q\textsubscript{10} in human plasma by high performance liquid chromatography

Vol. 22, No. 6, 2009

(S/N=10), the linearity between the concentration and peak height is from 0.1 to 2.0 mg/L. Twenty-four randomly selected plasma samples from apparently healthy, 27 to 44 year old individuals (males and females) were analyzed for total CoQ\textsubscript{10}. The average level in these subjects was 0.62±0.13 mg/L with the range of 0.41-0.98 mg/L. This method has a specific and a sufficient limit of quantitation (LOQ) for analysis of CoQ\textsubscript{10} in human plasma in both a clinical study and research at laboratories.

**Key words:** coenzyme Q\textsubscript{10}, antioxidant, micronutrients

1. Introduction

Coenzyme Q\textsubscript{10} (CoQ\textsubscript{10}) is a lipid soluble compound that occurs in the mitochondria of animal and human cells and is synthesized by hydroxybenzoic acid which reacts with isopentenylpyrophosphate under an enzyme system in the line of mitochondria.\textsuperscript{1} It is a vital electron and a proton carrier which supports ATP synthesis in the mitochondrial inner membrane.\textsuperscript{2,3} Its first action in energy transduction is an electron accumulation from the dehydrogenases for substrates oxidized by the mitochondrial cristae membranes. Secondly, it encompasses a vectorial proton movement to establish a proton gradient across the membrane that can be coupled to ATP production.\textsuperscript{4}

CoQ\textsubscript{10} is beneficial for preventing cellular damage during myocardial ischemia and reperfusion and has been used orally to treat various cardiovascular disorders that include angina pectoris, hypertension, arrhythmia, and congestive heart failure. A decreased ratio of plasma CoQ\textsubscript{10} to low density lipoprotein (LDL) cholesterol could be associated with an increased risk of atherosclerosis.\textsuperscript{5} CoQ\textsubscript{10} has been suggested to have both anti-cancer and immune system enhancing properties when CoQ\textsubscript{10} tested in animals.\textsuperscript{6}

Various analytical techniques have been employed for CoQ\textsubscript{10} analysis in samples of a biological origin. For a quantitative CoQ\textsubscript{10} determination in the plasma, the most generally used method is spectrophotometer and high performance liquid chromatography (HPLC) with different methods of detection: ultraviolet (UV), electrochemical (ECD) or mass spectrometry (MS).\textsuperscript{7,10} However, HPLC-UV method has a lower limit of quantitation (LOQ) than spectrophotometer (LOQ=0.07 mg/L). Also, it has a sufficient LOQ for analysis of CoQ\textsubscript{10} in human plasma and lower cost than any other HPLC methods.\textsuperscript{10} Liquid-liquid extraction method is a common extraction method which has high recovery rate and a low cost, even though a preparatory process is more complicate than a solid phase extraction (SPE) column method.\textsuperscript{7,8,11}

In the present paper, our method modified procedure of Peter (2001).\textsuperscript{11} Procedure of Peter used 1-propanol for liquid-liquid extraction but we used n-hexane which is a common organic solution for liquid-liquid extraction. While procedure of Peter used ECD for the detection of CoQ\textsubscript{10} in human plasma but we used UV which has a low cost than ECD method and a sufficient LOQ for analysis of CoQ\textsubscript{10} in human plasma. In addition, whereas process of Peter used a reversed-phase Microsorb-MV column (150×4.6 mm, 5 µm) which has a short run time (RT) and not a good resolution (R=0.88), we used reversed-phase Hypersil ODS column (250×4.6, 10 µm). As a result, we got a better resolution (R=2.16). Its usefulness is illustrated in a group of healthy subjects who were examined in order to estimate CoQ\textsubscript{10} plasma levels in the regional population.

2. Materials and Methods

2.1. Materials
The Coenzyme Q\textsubscript{10}(CoQ\textsubscript{10}, standard) and coenzyme Q\textsubscript{9}(CoQ\textsubscript{9}, internal standard) was purchased from Sigma (St. Louis, USA), methanol, ethanol, n-hexane, all of HPLC or analytical grade were obtained from Merck (Darmstadt, Germany). All the containers were wrapped with aluminium foil to prevent from light exposure.
2.2. Sample
Twenty-four healthy male and female volunteers (27-44 years old) were selected from Seoul clinical laboratories. Venous blood was collected in a Vacutainer\textsuperscript{TM} Tube (Becton Dickinson) containing heparin as anticoagulant and mixed by gentle inversion 5-10 min. The plasma was separated by centrifugation (2000 g for 10 min) in the dark and stored in the frozen condition (-20\degree C) until subsequent assay.

2.3. Instrumentation
The HPLC system consisted of HP1100 pump, HP 1100 variable absorbance detector, HP1100 column heater, HP1100 autosampler and integration software was used HP chemstation (Hewlett Packard Inc., Germany). Column (Hypersil ODS, 10 µm, 250×4.6 mm) was purchased from Agilent Technologies (U.S.A).

A mobile phase was methanol:ethanol (85:15, v/v). Flow rate was 1.7 mL/min and the column temperature was set at 30\degree C. UV detector was set at 275 nm (Table 1).

2.4. Preparation of plasma samples
Frozen plasma samples were thawed at room temperature in the dark before analysis. Extractions were performed in 10 mL amber glass test tubes with stoppers. An aliquot of 80 µL internal standard (CoQ\textsubscript{9}, 2 mg/dL in absolute ethanol) was added into 1.0 mL of plasma and was mixed for 10 sec by a vortex mixer, and then the sample was deproteinized with 1.5 mL of methanol. The treated sample was statically placed in the dark for 10 min. Four mL of n-hexane was transferred to 10 mL amber glass test tubes and was dried at 25\degree C in the water bath under nitrogen gas stream. The residue was dissolved in the absolute ethanol 200 µL and was injected onto HPLC system.

An aliquot of 80 µL internal standard (CoQ\textsubscript{9}, 2 mg/dL in absolute ethanol) and 10 µL of CoQ\textsubscript{10} stock solution (0.00, 0.01, 0.05, 0.10, 0.20 mg/mL in absolute ethanol, respectively) were added to 1.0 mL of fresh plasma to prepare the calibration curves. Calibration curve was constructed in the concentration range of 0.1-2.0 mg/L. The peak-area ratio increments of CoQ\textsubscript{10}/CoQ\textsubscript{9} were plotted as a function of the concentration of CoQ\textsubscript{10}. Where the peak-area ratio increment was the difference value of “peak-area ratio of total CoQ\textsubscript{10}/CoQ\textsubscript{9}” minus “peak-area ratio of endogenous CoQ\textsubscript{10}/CoQ\textsubscript{9}”.

3. Results
Typical HPLC-UV chromatograms showed that
Analysis of coenzyme Q₁₀ in human plasma by high performance liquid chromatography

The endogenous CoQ₁₀ peak in fresh plasma appeared around at 16.76 min (Fig. 1A) and the retention time of internal standard CoQ₉ was about at 10.51 min (Fig. 1B). Chromatograms in Fig. 1A and B were obtained from fresh plasma without or with supplement of CoQ₁₀. Chromatogram in Fig. 1C was obtained from subject plasma that was supplemented with internal standard CoQ₉.

The method was applied to some real samples and in Table 2 the data which obtained for a group of normal subjects are presented. The average level in <30 subjects was 0.61±0.12 mg/L with the range of 0.46-0.81 mg/L and 30-39 subjects was 0.60±0.11 mg/L with the range of 0.41-0.78 mg/L and ≥40 subjects was 0.70±0.25 mg/L with the range of 0.54-0.98 mg/L. The average level in male subjects was 0.65±0.28 mg/L with the range of 0.44-0.98 mg/L and in female subjects was 0.61±0.09 mg/mL with the range of 0.41-0.81 mg/L.

The minimum concentration of CoQ₁₀ that could be quantitated in plasma was 0.02 mg/L. This was determined to noise ratio of approximately 10 based on signal. Calibration curve was \( Y = 1.8476C + 0.0142 \), \( Y \) = the peak-area ratio increment and \( C \) = sample concentration \((r = 0.9999, \text{Fig. 2})\). The absolute recoveries of CoQ₁₀ ranged 99.12±4.00% to 100.93±2.51% as showing Table 3, and the precision of intra-day and inter-day were shown in Table 4. The coefficient of variation \((C.V, \%)\) values ranged from 2.05% to 4.72% for intra-day assay, and from 2.45% to 3.86% inter-day assay.

### 4. Discussion

CoQ₁₀ is almost insoluble in water and is soluble in hot ethanol and is freely soluble in n-hexane. The determination method was established by improving the extraction recoveries. The use of methanol to precipitate protein in plasma and n-hexane to extract the CoQ₁₀ and CoQ₉ improved the extraction efficiency. CoQ₁₀ and the internal standard CoQ₉ are unstable under the light thus all the samples were wrapped with aluminium foil and treatments were carried out under the illumination of yellow light or in the dark. In addition, CoQ₁₀ is also unstable at the high temperature. It is found that there are peak of decomposed CoQ₁₀ in water bath at 40 °C but stable at 25 °C or at 30 °C under nitrogen gas stream for drying. Temperature of an analytical column influences on a chromatogram peak. From a column which set at
30 °C, we obtained an optical resolution rate and a clear peak for CoQ_{10} and CoQ_{10.12}

CoQ_{10} concentration has generally a decreasing tendency as people pass their twenties but in our study, it doesn't seem to follow the previous pattern.¹³ For that reason, we considered several certain factors which can affect the result such as a failure of diet control as a main reason, a different life-style and eating habits. However, CoQ_{10} concentration was significantly higher than patients with cardiomyopathies of unclear etiology and cardiovascular diseases significantly higher than patients with cardiomyopathies (0.27±0.02 and 0.23±0.02 mg/L, respectively).¹⁴

CoQ_{10} level of normal subjects were somewhat lower or higher than those found by other authors. For example, P. Kaplan (1991) obtained CoQ_{10} levels over a range of 0.26-1.02 mg/L in healthy men.¹⁵ There are also very mark differences between the examined groups of “normal” individuals so we called either sedentary subjects or enduractive athletes. Jonansen (1991) showed 0.69 mg/L CoQ_{10} with the range of 0.36-0.80 mg/L in healthy men, Karlsson (1991) estimated 0.60 mg/L in normal subjects, 0.4 mg/L in endurance athletes and 0.90 mg/L for sedentary subjects.¹⁶ It is also necessary to note that the differences in CoQ_{10} plasma levels mentioned above may be caused by the different life-style or nutritional habits of the analyzed groups reported as compared to those of this regional population.

In conclusion, we proposed a simple, a rapid and an isocratic HPLC method for determination of CoQ_{10} in human plasma. An extraction process using n-hexane as solvent allows a rapid and simple a sample extraction and minimizes oxidation of CoQ_{10} during samples processing. A chromatogram run takes only 20 min and the sample preparation dose not exceed 100 min. From the presented results, this optimized a method which provides excellent sensitivity, precision and accuracy for relatively high-throughput assessment of CoQ_{10} in human plasma. This method is suitable for research and it can be easily adapted for clinical testing purposes. Studies are in progress to establish reference intervals and to evaluate the clinical significance of plasma concentration of CoQ_{10} in several patient populations.
