Abstract

This study was conducted to evaluate the changes in porcine serum albumin (PSA), a major allergen, which occur when raw pork ham is marinated with kiwi or pineapple juice, and/or when the ham is pan broiled at 300°C for 4 min after marination. In this study, raw pork ham was soaked for 4 h or 8 h in marinades containing commercial marinating sauce only, commercial marinating sauce and 7% kiwi juice, or commercial marinating sauce and 7% pineapple juice. When the meat was marinated and then pan-broiled, pork ham protein was significantly denatured and hydrolyzed, and the level of PSA in the meat was significantly reduced. The PSA contents of pork broiled without marination, pork that had been marinated in commercial marinating sauce alone, pork that had been marinated in commercial marinating sauce with kiwi juice, and pork that had been marinated in commercial marinating sauce with pineapple juice, were 95.4, 43.3, 14.3, and 5.4 ng/mL, respectively (p<0.05). Marinating with pineapple juice was more effective than marinating with kiwi juice; and marination for 8 h was more effective than marinating for 4 h. These results indicate that the level of PSA in pork ham is effectively reduced, when the meat is first marinated in sauces that contain kiwi or pineapple extracts for 8 h, rather than 4 h, and then cooked. Further study is needed to determine whether marinated pork meat reduces allergenicity in vivo, as well.

Key words: porcine serum albumin, marinating, allergen, sandwich ELISA, pork ham

Introduction

The term food allergy is used to describe adverse immune responses to foods (Sicherer and Sampson, 2010). Food allergy rates vary by age, local diet, and various other factors. Food-induced allergic reactions are responsible for a variety of symptoms and disorders involving the skin and gastrointestinal and respiratory tracts and can be attributed to IgE-mediated, non-IgE-mediated, and mixed-type mechanisms. Recently, scientists have reported IgG antibody in food allergy patients and Fc receptor of IgG4 antibody on the surface of mast cell (Chen et al., 2008; Lee et al., 1993). Since then scientists also focus on IgG antibody to explain food allergy which is non-IgE mediated (Cho et al., 2001; Lee et al., 1993). Food allergens have a number of common characteristics: they are water-soluble glycoproteins, 10 to 70 kDa in size, and relatively resistant to acid, heat, and proteases (Sicherer and Sampson, 2010).

Pork is the most popular meat in Korea, and the level of pork meat consumption has increased in recent years. Pork meat consumption per capita in 2005 was 17.8 kg and rose to 19.2 kg in 2012 (Korea Meat Trade Association, 2014). However, a survey of urban preschool children revealed that pork was one of the ten foods most often associated with allergy, as the incidence of pork allergy among the children was 1.9% (Chung et al., 2001). Although the incidence seems low, the consequence is severe and results in anaphylaxis shock. Moreover, pork has been classified as a major food allergen (Kim et al., 2011) and, as per Article 10 of the Korea Food Sanitation Act, must be indicated as such on labels for food products.

The most well-known allergens from meat are serum albumin (66 kDa), gamma-globulin (60 kDa), and actin...
(42 kDa), as well as several additional proteins of various sizes (14, 18, 20, 45, and more than 60 kDa). These allergens are found in not only beef but also pork and lamb and can cause cross-reactivity among foods (Fiocchi et al., 2000). Purified porcine serum albumin (PSA) or extracts from unprocessed meats that contain PSA have been used not only to evaluate allergenic potential but also to study the feasibility of reducing allergenicity by means of heat processing (Kim et al., 2011).

Current management of food allergies consists of educating the patient to avoid ingesting the responsible allergen and to initiate therapy (e.g., by injecting epinephrine to treat anaphylaxis) in case of unintended ingestion (Sicherer and Sampson, 2010). However, heating is one of the most efficient methods to reduce allergenicity. Fisher (1982) reported the case of a patient who presented with anaphylactic symptoms after ingesting rare-cooked beef but who was able to tolerate well-cooked beef. Although treatment of meat with digestive enzymes has been reported to reduce the allergenicity of serum albumin from different species (Kim et al., 2011), there has been no specific study examining the effects of fruit enzymes and pan broiling at 300°C on altering the allergen PSA. Therefore, the aim of this study was to use SDS-PAGE, immunoblotting, and sandwich ELISA to determine the effect of pan broiling and/or marinating with kiwi or pineapple juice on the level of PSA in pork meat.

Materials and Methods

Marination and pan broiling

Raw pork ham, commercial marinating sauce, kiwis, and pineapples were purchased from a local market. Raw pork ham was soaked for 4 h or 8 h in a marinade containing 27% commercial sauce only, commercial sauce with 10% kiwi juice, or a commercial sauce with 10% pineapple juice (Table 1). Then, it was either analyzed immediately or subjected to pan broiling on a hot plate for 4 min at 300°C prior to analysis (Fig. 1). In addition, pork that was pan broiled without prior marination was also examined.

Porcine serum albumin (PSA) extraction

PSA was extracted from the pork using the method described in Wang et al. (2002), with a slight modification. Twenty grams of meat was added to 40 mL of 0.01 M phosphate-buffered saline (PBS, pH 7.3). Next, the meat was homogenized at 10,000 rpm for 30-60 sec and then centrifuged at 16,000 g for 30 min. The supernatant was filtered using Whatman No. 1 filter paper and then used for further experiments.

Commercial PSA and antibodies

Commercial PSA and a horseradish-peroxidase (HRP)-conjugated rabbit anti-goat-IgG antibody were purchased from Sigma Chemical Co. (USA). A goat anti-PSA IgG antibody was obtained from Bethyl Laboratories Inc. (USA).

SDS-PAGE

Proteins from pork meat extracts were separated according to their molecular weights on 12% separating gels and 5% stacking gels. Prior to loading, the samples were analyzed for protein content using a BCA protein assay kit (B9643, Sigma). Coomassie Brilliant Blue R 250 (Sigma) was used for visualization (Laemmli, 1970). Electrophoresis was performed using a miniPAGE (page Run, AE-6531; ATTO, Japan) system at 100 V for 3 h. The sizes of the protein bands were identified using a standard Prosi prestained protein marker (GenDEPOT, USA).

Immunoblotting assay

After SDS-PAGE, proteins were transferred to methanol-activated polyvinylidene difluoride (PVDF) membranes and then to immobilization paper (Shleicher & Schuell, USA) for 30 min at 200 mA using an electrophoresis power supply (Northeastern Science Company, USA) and a Mini Trans-Blot Transfer Cell (Bio-Rad Laboratories). The PVDF membranes were blocked with 3% gelatin in TBS-T (20 mM Tris, 137 mM NaCl, pH 7.6, with 0.1% Table 1. Tween-20) for 2 h at RT and then washed in TBS-T 3 times for 10 min each time. The membranes were then incubated with the primary antibody (diluted 1:1000 in TBS-T) overnight with rocking at 4°C. Then the membrane was washed again in TBS-T 3 times for 10 min each time. Then, an HRP-labeled rabbit anti-goat IgG antibody (diluted 1:3000 in TBS-T) was added to the membranes, which were then incubated for 1 h at RT and subsequently washed 3 times in TBS-T. Antigen-antibody complexes were detected by chemiluminescence (Santa Cruz Biotechnologies). Chemiluminescence signals were observed using a ChemiDoc (Vilber Lourmat, France).

Sandwich ELISA assay

For the sandwich assay, 96-well flat-bottomed microplates were coated overnight at 4°C with 100 µL/well of 0.05 M carbonate-bicarbonate buffer (pH 9.6) containing an affinity-purified anti-PSA antibody (1 µL of the affinity-purified antibody was diluted in 100 µL coating buffer for each well to be coated). The plates were then washed 5 times in TBS containing 0.05% Tween 20 (pH 7.6). After washing, the wells were blocked with 200 µL/well of a blocking solution consisting of 1% gelatin in TBS and then incubated for 1 h at RT. After washing again, 100 µL/well of a standard at concentrations ranging from 7.8 to 500 ng/mL. Standards, buffer blanks (assay buffer), and sample extracts were incubated for 1 h at RT under gentle shaking in triplicate on each plate. After washing, the plates were incubated with 100 µL/well of HRP-detection antibody (diluted 1:100,000) for 1 h at RT. All dilutions were performed in assay buffer, and the plates were sealed with plate-sealing film during incubations. After a final wash, each well was incubated with 100 µL/well TMB substrate solution. The plate was developed in the dark at room temperature for 15 min. Color development was stopped by the addition of 100 µL/well of ELISA stop solution (0.18 M H₂SO₄). The plate was evaluated within 30 min of stopping the reaction by measuring the absorbance at 450 nm using a Spectra Max M₂e Microplate Reader (Molecular Devices, USA).

Statistical analysis

Data were analyzed using the general linear model, and significant differences were determined with Duncan’s multiple range test at $p<0.05$ using SAS software (SAS Institute Inc., USA).

Results and Discussion

Marinating and broiling pork ham

Fig. 1 shows a diagram of experimental treatments and the sample preparation procedure used in this study. Raw

![Diagram showing experimental treatments and sample preparation procedure.](image)
pork ham (RP) was soaked for 4 h or 8 h in a marinade containing 27% commercial sauce only (RPM), commercial sauce with 10% kiwi juice (RPMK), or a commercial sauce with 10% pineapple juice (RPMP) (Table 1). Then, it was either analyzed immediately or subjected to pan broiling prior to analysis and designated as BP, BPM, BPMK, and BPMP. In addition, pork that was pan broiled without prior marination was examined.

SDS-PAGE profiles of PSA after marination

Fig. 2 shows the protein profiles of pork that was marinated for 4 or 8 h in commercial sauce only, commercial sauce with kiwi juice, or commercial sauce and pineapple juice and then either analyzed immediately or pan broiled prior to analysis. An intense band corresponding to the size expected for PSA (approximately 66 kDa) was observed in extracts from raw pork meat that had been marinated with commercial sauce alone, commercial sauce and kiwi juice, and commercial sauce and pineapple juice for both 4 and 8 h. However, broiling pork meat at 300°C for 4 min after marination significantly decreased the intensity of the band, although it was not completely eliminated, and also significantly reduced the intensities of other bands at approximately 6 kDa, 17 kDa, 26 kDa, and 43 kDa. In addition, marinating for 8 h caused an increase in the intensity of a band that was less than 6 kDa in size. Interestingly, it has been reported that the allergenicity of a protein may be either decreased or increased by food processing steps as epitope structures are destroyed or new epitopes are formed (Besler et al., 2001; Kim et al., 2011).

Kiwi and pineapple are the most popular fruits used to tenderize meat. Actinidin is a cysteine protease present in kiwi fruit, and it belongs to the same class of enzymes as ficin, papain, and bromelain. Actinidin hydrolyzes a wide range of myofibril proteins, including actomyosin (myosin and actin; 223 and 42 kDa, respectively), and Z-disk associated proteins such as nebulin and titin (650-3200 kDa), filamin (280 kDa), actinin (100 kDa), and desmin (53 kDa), although in a nonselective manner (Ha et al., 2012). When the tenderizing effects of actinidin and papain on bovine semitendinosus muscle were compared, a higher amount of actinidin was needed in order to produce tenderness equivalent to that observed using papain, although, unlike papain, actinidin did not overtenderize the meat. In addition, actininide treatment caused myosin heavy chain proteins to be degraded and led to changes in the intensities of bands associated with other myofibrillar proteins (Ha et al., 2012). Moreover, treatment with actinidin did not produce off flavors or odors in the meat.

359

and did not cause surface “mushiness” (Kim and Taub, 1991). Bromelain (a cystein protease) is an enzyme mixture extracted from pineapple. Many studies reported that enzyme activity of bromelain is sustained without a marked decrease up to 80°C (El-Gharbawi and Whitaker, 1963; Tappel et al., 1956). Bromelain first degrades 40% of the collagen in the sarcolemma followed by degradation of myosin in the myofibrillar component (Kang and Rice, 1970; Wang et al., 1958).

PSA expression in pork after marinating and broiling

Levels of PSA in pork meat after marinating for 4 h with fruits extracts and subsequent pan broiling were determined by immunoblotting and are shown in Fig. 3. PSA was detected in both RP and RPM (Fig. 3(A)). However, the level of PSA was significantly reduced when marination and pan broiling were combined. Moreover, the length of marination time has an effect on the amount of PSA degraded, since the levels of PSA in samples after 8 h of marination (Fig. 3(B)) were less than those of samples marinated for 4 h (Fig. 3(A)). In addition, marination with pineapple juice, which contains bromelain, caused a more significant decrease in PSA than marination with kiwi juice. This may due to a difference in the activities of enzymes in kiwis and pineapples. Kim et al. (2010) suggested that the protease effect of crude extract from the pineapple on casein and myofibrillar protein was higher than that of extracts from kiwi fruits. In this study we focused on the change of porcine serum albumin amounts of pork meat by fruits juice with marination and heating and did not check enzyme activities in fruits juice. Further study is needed to evaluate exact change of enzyme activities during cooking and preparation. Sakai et al. (1998) reported that peptides less than 10,000 Da with very low IgE-binding activity could be produced after enzymatic treatment of pork gelatin (heat-denatured collagen) with collagenase. In this study, we found that heating and 8 h of marination with pineapple juice significantly decreased IgG binding activity. This result is well supported by the results from a study by Kim et al. (2011) on the effect of digestive enzymes such as pepsin and trypsin on the allergenicity of pork sausages. In that study, it was reported that pepsin and trypsin significantly reduced IgG binding activity up to 20%.

To determine the exact concentration of PSA in the treated meat, sandwich ELISA assays were performed (Table 2), and the R squared value of the mean standard curve of PSA was found to be 0.995. RP had a significantly higher level of PSA than broiled pork meat. The level of PSA in RPMP was significantly less than that RPM and RPMK. Interestingly, the levels of PSA after 8 h of marination in

Fig. 3. Immunoblotting assay for PSA from raw and broiled pork meat protein after marinating for 4 or 8 h with commercial sauce alone, commercial sauce with kiwi juice, and commercial sauce with pineapple juice. (A) Immunoblotting profile of pork ham marinated for 4 h with or without subsequent broiling. (B) Immunoblotting profile of pork ham marinated for 8 h with or without subsequent broiling. Lane PSA, porcine serum albumin; lane T1, raw pork ham; lane T2, broiled pork ham; lane T3, raw pork ham marinated with commercial sauce alone; lane T4, pork ham marinated with commercial sauce alone and then broiled; lane T5, raw pork ham marinated with commercial sauce and kiwi juice; lane T6, pork ham marinated with commercial sauce and kiwi juice and then broiled; lane T7, raw pork ham marinated with commercial sauce and pineapple juice; lane T8, pork ham marinated with commercial sauce and pineapple juice and then broiled.
both raw and broiled meat were significantly reduced. The PSA content of BP, BPM, BPMK, and BPMP was 95.4, 43.3, 14.3, and 5.4 ng/mL, respectively (p<0.05). These results shows that whereas marinating time and the use of pineapple juice in the marinade are important factors for reducing the level of PSA, cooking at 300°C has the most impact.

Conclusions

These results demonstrate that both cooking and marination with juices that contain cysteine proteases from the papain family such as actinidin from kiwi and bromelain from pineapple are effective for reducing levels of PSA in pork, and that the most effect method is to cook pork after marinating it in pineapple juice for 8 h.
