This study has investigated whether extracellular HSP90 predisposes vascular smooth muscle cells (VSMCs) to pro-inflammatory phenotype. Exposure of rat aortic smooth muscle cells to HSP90 not only enhanced IL-6 release but also profoundly induced IL-6 transcript via promoter activation. HSP90-induced IL-6 promoter activation was suppressed by dominant-negative forms of Toll-like receptor (TLR)-4 and myeloid differentiation factor 88 (MyD88), but not by dominant-negative forms of TLR-3 and TIR-domain-containing adapter-inducing interferon-β (TRIF). Curcumin, which inhibits dimerization of TLR-4, also attenuated the IL-6 induction by HSP90. Mutation at the NF-κB or C/EBP-binding site in the IL-6 promoter region suppressed the promoter activation in response to HSP90. The present study proposes that extracellular HSP90 would contribute to inflammatory reaction in the stressed vasculature by inducing IL-6 in VSMCs, and that TLR-4 and NF-κB would play active roles in the process.

Key words : Interleukin 8, heat shock protein 90, toll-like receptor, vascular smooth muscle cell

Introduction

Heat shock proteins (HSPs), the highly conserved molecules which participate in protein folding and assembly, are crucial for correct transportation of proteins through the cell [21]. Among the families of HSPs grouped according to their molecular weight, HSP60 and HSP70 have been the subject of extensive studies with regard to immunogenic and inflammatory properties in association with atherosclerosis [16,19]. HSP60 localizes selectively in atherosclerotic lesions as opposed to non-atherosclerotic regions of the arterial wall. In advanced atherosclerotic lesions, HSP70 is over-expressed in several cell types, including monocytes, macrophages, dendritic cells and smooth muscle cells [7,29]. HSPs are normally intracellular whereas HSP90 is secreted from vascular smooth muscle cells (VSMCs) during oxidative stress and from necrotic, not apoptotic, macrophages [2,11]. However, it is not reported whether the secreted HSP90 affects VSMCs in terms of inflammatory property.

VSMCs reside mostly in the media of healthy arteries and regulate vascular tone. In atherosclerosis, VSMCs undergo phenotypic and cellular changes thought to be crucial in the development of atherosclerotic plaque, and thus producing cytokines and excessive extracellular matrix proteins [12,13]. It is evident that interleukin-6 (IL-6) plays an active role in this process. IL-6 induces an acute phase response and stimulates lymphocyte proliferation as well as differentiation of B cells and their antibody production [9]. The effects of this cytokine also include growth- and differentiation-inducing activities of nonlymphoid cells, particularly of VSMCs and vascular endothelial cells [6,17]. Findings from previous clinical studies have shown that IL-6 can be a risk factor for the development of atherosclerosis and restenosis. Plasma levels of IL-6 are enhanced in patients with unstable angina and with restenosis independent of other risk factors [10,27]. Thus, understanding IL-6 regulation is important in vascular biology due to close association of this cytokine with vascular diseases.

VSMCs produce IL-6 and the production is enhanced in response to platelet-derived growth factor-BB, thrombin, angiotensin II [14], and mechanical stress [28]. The presence of IL-6 protein and mRNA has been observed in human normal and atherosclerotic arterial walls. When the cytokine has been detected by immunohistochemical staining, the normal intima presents only cellular deposits. In contrast, intimal thickening and fibrous plaque show extended intracellular and extracellular deposits of IL-6 [18,20]. These findings suggest that some local factors induce synthesis of this cytokine
in the cells of the atherosclerotic arterial wall.

To explore the potential role of secreted HSF90 in vascular inflammation, we investigated whether extracellular HSF90 induces IL-6 in VSMCs, and found that aortic smooth muscle cells (AoSMCs) exhibited IL-6 up-regulation via transcriptional activation in response to HSF90. Furthermore, the involvement of Toll-like receptors (TLRs) and transcriptional activation in response to HSF90. The effects of HSF90 on IL-6 transcript and protein in VSMC

Materials and Methods

Cell culture and reagents

A7r5 rat AoSMCs (American Type Culture Collection, Manassas, VA) were cultured in Dulbecco’s modified Eagle’s medium-high glucose (DMEM) supplemented with 10% fetal bovine serum (FBS), 50 units/ml penicillin and 50 μg/ml streptomycin in a humidified atmosphere of 5% CO₂. Recombinant HSF90 was purchased from ProSpec-Tany Technogene Ltd (Rehovot, Israel). Resveratrol (3,4',5-trihydroxy-trans-stilbene) and curcumin were purchased from Sigma-Aldrich (St. Louis, MO). The reporter plasmid containing a 651-bp fragment of the IL-6 gene promoter region (pIL-6-Luc) located directly upstream of the transcriptional start site, as well its mutant constructs were kindly provided by Dr. Oliver Eickelberg [4]. Plasmids encoding dominant-negative forms of TLR pathway were purchased from Invivogen (San Diego, CA).

Enzyme linked immunosorbent assay (ELISA) of IL-6

The cytokine content of culture supernatant was determined through the use of commercially available microtiter plate ELISA kit according to the manufacturer’s instructions (Biotrak ELISA, Amersham, Buckinghamshire, UK). Cells were serum starved for 6 hr and exposed to HSF90 prior to isolation of culture medium. The isolated culture medium and IL-6 standards were added to the microtiter plate pre-coated with a monoclonal antibody against IL-6. After incubation for 1 hr, the plate was washed. Next, the plate was incubated with an enzyme-linked polyclonal antibody specific for IL-6. The substrate solution was added after several washes, and the color intensity was read.

Reverse transcription (RT) - polymerase chain reaction (PCR)

Total RNAs were reverse-transcribed for an hour at 42°C with Moloney Murine Leukemia Virus reverse transcriptase, followed by PCR analysis. For PCR analysis, primers for IL-6 were 5'-AGTTGCCTTCTTGGGACTGA-3' (forward) and 5'-CAGAATTTGCATTGCACAAAC-3' (reverse). Products were size-separated by electrophoresis on 2% agarose gels and visualized by ethidium bromide staining. To ensure that correct sequences had been amplified, amplification products were sequenced.

Transient transfection and luciferase assay

Rat AoSMCs were seeded in 100-mm culture dishes 24 hr before transfection. Cells were transfected with 10 μg IL-6 reporter plasmid and 3 μg β-galactosidase plasmid using Lipofectamine. Cells were then re-fed DMEM containing 10% FBS 6 hr post-transfection and incubated overnight. Transfected cells were exposed to 500 ng/ml HSF90 for the indicated time periods. Luciferase activity was measured using a luciferase assay kit (Promega, Madison, WI) with signal detection in a luminometer and normalized to β-galactosidase activity.

Statistics

Statistical analyses were performed by ANOVA, and p<0.05 was considered statistically significant.

Results

The effects of HSF90 on IL-6 transcript and protein in VSMC

To investigate the effects of HSF90 on IL-6 expression in VSMCs, the level of IL-6 transcript was examined by RT-PCR after exposure of rat AoSMCs to recombinant HSF90. Figure 1A shows that IL-6 transcript was elevated in the presence HSF90. The elevation was observed as early as 6 hr post-treatment and persisted up to 24 hr after treatment. We also examined by ELISA whether VSMCs released IL-6 protein, and found that secreted IL-6 increased profoundly in response to HSF90 (Fig. 1B). The amount of IL-6 in the medium increased from 90 pg/ml to 370 pg/ml in the presence of HSF90. Reporter gene assays were carried out to investigate whether HSF90 increased IL-6 transcript via promoter activation. Rat AoSMCs were transfected with the IL-6 reporter plasmid, and luciferase activity was assessed in the presence or absence of HSF90 (Fig. 1C). Compared with control exposed to BSA, luciferase activity increased by 2.1-fold in the presence of HSF90, indicating...
IL-6 promoter was affected by co-transfection with dominant-negative forms of TLR-4 (Fig. 2A) and myeloid differentiation factor 88 (MyD88) (Fig. 2B). Of the two, dominant-negative MyD88 profoundly inhibited promoter activation of IL-6 gene. Co-transfection with dominant negative forms of TLR-3 and TIR-domain-containing adapter-inducing interferon-β (TRIF), however, did not inhibit HSP90-induced IL-6 gene activation. The effects of phytochemicals known to modify TLR-4 signaling on HSP90-induced IL-6 up-regulation were investigated by reporter gene assays (Fig. 3A). Curcumin and resveratrol significantly suppressed the HSP90-induced IL-6 promoter activity. The suppression was more significant in the presence of curcumin. Pre-treatment with curcumin suppressed the HSP90-induced IL-6 promoter activity approximately to that of control. When the effects of the two phytochemicals on IL-6

Data are expressed as means±SDs (n=3 replicates/group). * P<0.01 vs. control.

Involvement of TLR-4 pathways in IL-6 promoter activation

To investigate roles of TLRs in HSP90-induced promoter activation of IL-6 gene, a reporter gene assay was carried out after transfection of rat AoSMCs with the IL-6 reporter plasmid in combination with dominant-negative forms in TLR pathways. HSP90-induced luciferase activity driven by that HSP90 promoted IL-6 transcriptional activity.

Fig. 2. Involvement of TLR-4 in the activation of IL-6 gene by HSP90 in VSMCs. The IL-6-Luc plasmid was co-transfected into rat AoSMCs with the indicated dominant-negative forms of TLRs (A) or with dominant negative forms of TLR-4 adaptor molecules (B). After stimulation with HSP90 (500 ng/ml, for 6 hr), luciferase activity was determined and normalized to β-galactosidase activity. Induction was calculated relative to the activity of control cells. Data are expressed as means±SDs (n=3 replicates/group). * P<0.01 vs. control. **P<0.01 vs. pCMV.

Rat AoSMCs transfected with the wild-type pIL-6-Luc construct or the indicated mutant construct were stimulated with HSP90 (500 ng/ml, for 6 hr) and processed for luciferase and β-galactosidase assays. Induction was calculated relative to the activity of control cells transfected with wild-type IL-6 promoter. Data are expressed as means±SDs (n = 3 replicates/group). *P<0.01 vs. pCMV. **P<0.01 vs. pIL-6-Luc. (B) The effects of IκB on IL-6 release. Rat AoSMCs were infected with indicated recombinant adenoviruses (MOI: 100) and stimulated with HSP90 (500 ng/ml, for 12 hr). The amount of secreted IL-6 was measured using ELISA. Data are expressed as means±SDs (n = 3 replicates/group). *P<0.01 vs. LacZ -HSP90. **P<0.01 vs. LacZ +HSP90.

protein were examined, resvaratrol and curcumin significantly attenuated IL-6 release from VSMCs (Fig. 3B).

Roles of NF-κB and C/EBP in HSP90-induced IL-6 promoter activation in VSMCs

To investigate roles of the transcription elements in HSP90-induced IL-6 promoter activation, reporter gene assays were carried out after transfection of rat AoSMCs with an IL-6 reporter plasmid mutated at the NF-κB- or C/EBP-binding site (Fig. 4A). HSP90 significantly increased the luciferase activity. Mutation at the NF-κB- or C/EBP-binding site profoundly inhibited the luciferase activity induced by HSP90 which indicates that the NF-κB- and C/EBP-binding sites are necessary for activation of IL-6 by HSP90 in VSMCs. To obtain further evidence for the role of NF-κB in HSP90-induced IL-6 up-regulation in VSMCs, the amount of secreted IL-6 in response to HSP90 was determined by ELISA after infection with recombinant adenoviruses expressing IκB and β-galactosidase (Fig. 4B). HSP90 elevated IL-6 release from VSMCs. However, the
HSP90-induced IL-6 release was significantly attenuated by gene delivery of IκB, an endogenous inhibitor of NF-κB.

Discussion

The present study focused on the expression of IL-6 and regulation of IL-6 gene in AoSMCs in response to extracellular HSP90. When VSMCs were exposed to HSP90, IL-6 transcripts were significantly increased, and the luciferase activity driven by the IL-6 gene promoter was elevated, which indicates that extracellular HSP90 transactivates IL-6 gene. Moreover, HSP90 enhanced release of IL-6 protein from VSMCs. Taken together, these data indicate that HSP90 upregulates IL-6 at transcriptional and post-translational levels.

The association of TLRs with vascular diseases has been demonstrated. Compared with normal arteries, expression of TLRs, such TLR-1, -2, and -4, are markedly enhanced, and a considerable proportion of TLR-expressing cells are activated in the human atherosclerotic lesion [3]. Among the subtypes of TLRs, TLR-4 seems to be closely associated with atherosclerosis, as knockout of TLR-4 or its adaptor molecule, MyD88, has been reported to block inflammatory response and proliferation of VSMCs in the atherosclerotic lesion [5,15]. HSPs can act as an endogenous ligand for the TLRs [1]. Among the subtypes of TLRs, expression of TLR-3, and -4 has been detected in human VSMCs [23,24]. TLR-4, which is the most abundant TLR in human VSMCs, transmits signals through MyD88-dependent and -independent (e.g., via TRIF) pathways after recognition of LPS, an exogenous ligand [1,8]. When the roles of the TLRs in HSP90-mediated activation of IL-6 gene were examined using dominant-negative constructs, IL-6 promoter activity was attenuated by dominant-negative TLR-4 and MyD88, but not by dominant-negative TLR-3, TRIF, indicating major roles of TLR-4 and MyD88 in activation of IL-6 gene by HSP90. We also investigated the effects of phytochemicals, which modulate TLR-4 signaling, on IL-6 up-regulation. Curcumin inhibits ligand-induced and ligand-independent dimerization of TLR-4, and thus inhibited both MyD88- and TRIF-dependent pathways in LPS-induced TLR-4 signaling [26]. We found that curcumin inhibited promoter activation of IL-6 gene and release of IL-6 protein by HSP90. Taken together, these findings indicate HSP90 is likely to induce IL-6 expression in VSMCs via MyD88-dependent TLR-4 pathway.

The IL-6 promoter region contains motifs for transcription element of NF-κB, C/EBP, and AP-1 [22]. Thus, it was determined which transcription elements were responsible for promoter activation in response to HSP90 using mutant IL-6 reporter plasmids. The mutation at NF-κB- or C/EBP-binding site significantly attenuated promoter activity, indicating active role of NF-κB- and C/EBP in IL-6 induction. This finding agrees to the fact that the signal from TLR-4 activates NF-κB [1,8] and to the result of this study that IL-6 induction by HSP90 was significantly attenuated by resveratrol, which inhibits NF-κB activation [25]. Whether the inhibition of transcription factor NF-κB played a role in IL-6 release was further investigated using recombinant adenoviruses. Over-expression of IκB attenuated the IL-6 release. Taken together, these data indicate that NF-κB is necessary for the HSP90-mediated IL-6 up-regulation in VSMCs.

In the present study, we demonstrated that extracellular HSP90 induces IL-6 expression in VSMCs via TLR-4 signaling pathway. This finding suggest that HSP90, which is secreted by oxidative stress and during necrotic cell death, would upregulate IL-6 in VSMCs via TLR-4 pathway, and thereby would contribute to the inflammatory reaction in the damaged vasculature.

초록 : 혈관평활근세포에서 HSP90에 의한 IL-6 발현에 TLR-4와 NF-κB의 작용

임병용 · 김강성 · 김관회
(부산대학교 의학전문대학원 약리학교실)

HSP90에 노출된 혈관평활근세포에서 IL-6 transcript가 증가하고, IL-6 단백질의 분비가 증가하며, 또한 IL-6 유전자의 promoter가 활성화되었다. HSP90에 의한 IL-6 유전자의 promoter 활성화는 dominant negative 형태의 TLR-4와 MyD88에 의하여 크게 감소되었지만, dominant negative 형태의 TLR-3와 TRIF의 영향을 받지 않았다. 그리고 TLR-4의 이합체화(dimerization)를 저해하는 curcumin은 HSP90에 의한 IL-6의 분비 및 IL-6 유전자 promoter 활성화를 억제하였다. 그리고 IL-6 유전자의 promoter의 NF-κB 또는 C/EBP-binding sequence에 변이는 HSP90에 의한 IL-6 유전자의 promoter 활성화 억제하였다. 이러한 결과는 혈관평활근세포에서 HSP90에 의한 IL-6 유전자 활성화에 TLR-4와 NF-κB가 관여함을 의미한다.
