Abstract

In this paper, we present an algorithm to extract features about disease region in digital stomach images. For feature extraction, DCT coefficients of gastrointestinal imaging matrix was obtained. DCT coefficient matrix is concentrated energy in low frequency region, we were extracted 128 feature parameters in low frequency region. Extracted feature parameters can using for differential compression of PACS and, can using for input parameter in CAD.

Key Words : Digital Stomach Image, Image plate, Feature Extraction, DCT

I. Introduction

Now, a study about image and multimedia information system is actively progressed. Using these results of a study, many researchers are studying for applying to the medical fields. Many researcher is concerning about PACS which is able to process mass digital medical image data[1]. Especially, success of modern hospitals depends on excellent development and management of PACS. If PACS is popularized and ultrahigh speed communication line is equipped, all patients can be supported to excellent doctors using the PACS and ultrahigh speed communication line. And it is able to improve the level of medical diagnosis. If doctor use sample DB(Database) medical image, discrimination about medical image is automatically made possible. So in this paper we present an algorithm to extract features about disease region in digital stomach image. The results of study will be applied...
to PACS with automatic discrimination system about medical image.

II. Acquisition of Medical Image

An image plate is used for the generation of digital medical image. An image plate consists of the complex of bariumfuloroharide including uropum in the rare-earth element, over coating protect layer on surface[2][3].

Fig. 1 shows the flowchart of medical image generation on image plate. First, digital medical image is obtained on image plate. Second, medical image on image plate is recoded to memory by scanning an image plate with laser beam. Image plate is initialized by beaming an white light for recycling. A resolution is decided by diameter of laser spot.

A resolution of image plate is about 10 times than the method using a film. The acquired medical images are easy transmitted through LAN, WAN, and Internet.

III. Extracting the Feature Parameters using DCT

The many kinds of feature parameters from DCT coefficients obtained after DCT with input medical image are extracted in low frequency domain because the energy is concentrated at low frequency domain[4][5][6][7]. We divide the DCT coefficients into $8 \times 8$ block after performing DCT. One block consists fo $32 \times 32$ pixels. Fig. 2 shows the flowchart for extracting many kinds of feature parameters about disease regions from DCT coefficients after performing DCT.

The detail steps for extracting feature parameters from coefficient after DCT show as follows.

Step 1 : Extracting DCT coefficients obtained from medical image.

Step 2 : Dividing DCT coefficients into 64 blocks after DCT.
Step 3: The frequency feature parameters 32 are extracted in block(0,0).

Step 4: The angle feature parameters 16 are extracted in block(0,0).

Step 5: The translation feature parameters 16 are extracted in block(0,0).

Step 6: The amplitude feature parameters 64 of each block are extracted in all blocks.

Therefore 128 feature parameters is extracted.

The table 1, table 2 and table 3 show the methods of feature extracting in block(0,0).

The table 4 shows the positions of blocks for extraction amplitude feature parameters.

IV. Experiment and Result

The experimental environment is as follows.

First, we extracted the feature parameters from DCT coefficients of normal image. Second, we extracted the feature parameters from DCT coefficient of image including disease region. Then, we extracted the difference from DCT coefficients of two medical images. The differences of two input image are that the gastric mucous membrane is concentrated in disease region, disease region is projected above, and gastric outline is depressed. Thus the feature parameters of frequency, angle, translation, and amplitude feature extracted from DCT coefficients were changed at disease region.

(a) Barium relief(normal) (b) Double contrast(normal)
We were compared disease image and normal image using extracted feature parameter. And, we were shown of result as following figures.

Figure 4 shows the results of barium relief a comparison of images.

Figure 5 shows the results of double contrast a comparison of images.

Figure 6 shows the results of full filling a comparison of images.

V. Conclusion and Discussion

In this paper we proposed the algorithm about feature extraction of disease regions, we obtained the conclusion like the follows.
1. For feature parameters, we used the images of two types. One type is normal medical image. Another type is medical image including the disease region. We extracted the DCT coefficients from each input images.

2. The total parameters are 128. In block(0,0), we extracted 32 frequency feature parameters, 16 angle feature parameters, 16 translation feature parameters and 64 amplitude feature parameters.

3. We obtained the difference between normal input medical image and input medical image including the disease region.

4. Comparing the extracted features was able to get meaningful results.

The results of this paper will be able to using differential compression in PACS and, using of input parameters of CAD[8][9].
