ABSTRACT

Two new marine sponges in family Halichondriidae, Halichondria ulleungensis n. sp. and H. hongdoensis n. sp. are collected from Ulleungdo Island and Hongdo Island, Korea by SCUBA diving during 2003-2004. H. ulleungensis n. sp. is similar to H. corrugata Diaz, Pomponi and van Soest, 1993 in the type of spicule, but it is different in growth form and choanosomal skeleton. The growth form is encrusting, with numerous erected cylindrical tube, comparing with massive-lobate of H. corrugata. The choanosomal skeleton is confused with loosely arranged oxe a tract, comparing with densely tracts with many spicules of H. corrugata. H. hongdoensis n. sp. is similar to H. surubicunda Hoshino, 1981 in type of spicule and growth form, but this species has two kinds (thick and thin) of oxea.

Key words: Halichondria, new species, Halichondrida, Halichondriidae, Korea

INTRODUCTION

The marine sponges of the family Halichondriidae Gray, 1867 have choanosomal skeleton consisting of high density of spicules arranged in vague, ill-defined, directionless tracts and spicules in confusion (Hooper et al., 1997). It consists of 11 genera, Azinyssa, Amorphinopsis, Ciocalpata, Ciocalypta, Epipolaxis, Hymeniacidon, Halichondria, Lamispongia, Spongiosorites, Topesnia and Vosmeeria (Hooper and van Soest, 2002). Among them, the genus Halichondria Fleming, 1828 is characterized by euctosomal skeleton which consists of thin, tangential, clearly detachable membrane, containing single oxeas or vague bundles of oxeote spicules, supported by choanosomal columns of oxeas traversing subdermal spaces. Choanosome has the appearance of a disordered loose reticulation, and spiculate tracts are poorly defined (Hooper, 1994). Megascleres have exclusively oxeas or derive in a wide size range. About 110 species distributed over all regions and habitats (Hooper and van Soest, 2002). Five species of Halichondria have been reported from Korean waters (Kim et al., 1968; Rho and Lee, 1976; Kang and Sim, 2008).

SYSTEMATIC ACCOUNTS

Phylum Porifera Grant, 1836
Class Demospongiae Sollas, 1885
Order Halichondridae Gray, 1867
Family Halichondriidae Gray, 1867

1. Halichondria ulleungensis n. sp. (Fig. 1)

Material examined. Holotype (Por. 87), Ssangencho, Ulleungdo Island, 27 Aug. 2003, SCUBA 20 m deep, K.J. Lee, deposited in the Department of Biological Sciences, Hannam University, Daejeon, Korea.
Description. Encrusting with numerous erected cylindrical tube, 4.5 cm high. S sized up to 4 x 3 cm wide and 1 cm thick. Oxeas, 0.5-1 cm in diameter, opened at top of each tube. Color yellow in life which gradually changes to ivory in alcohol. Texture soft. Surface smooth. Ectosomal skeleton

MATERIALS AND METHODS

The sponges were collected from Ulleungdo Island and

Hongdo Island, Korea by SCUBA diving during 2003-2004. Specimens were fixed in 95% or 99.9% ethanol. Spicules were observed by light microscope (Carl Zeiss Axioskop II). Identification was done on the basis of external features, shape, structure of skeleton, and size and form of spicules. Thin free-hand sections were made with specimens hardened in alcohol using a surgical blade in order to observe the structure of the skeleton. Spicules were prepared by dissolving a piece of sponge in sodium hypochlorite and were examined with SEM (Rützler, 1978; Hooper, 1996). The holotypes are deposited in Department of Biological Sciences, Hannam University, Daejeon, Korea.

**Spicuets.**

Thick oxea ............... 330-520 × 8-12.5 µm

Thin oxea .................. 290-430 × 2.5-6 µm

**Etymology.** This species is named after the type locality,
Ulleungdo Island, Korea.

*Remark.* *Halichondria hongdoensis* n. sp. is similar to *H. corrugata* Diaz, Pomponi and van Soest, 1993 in the type of spicules, but it is different in the growth form and choanosomal skeleton. Growth form is encrusting, with numerous erected cylindrical tube, comparing with massive-lobate of *H. corrugata*. The choanosomal skeleton is confused with loosely arranged oxea tract, comparing with dense tracts with many spicules of *H. corrugata* (Table 1).

2. *Halichondria hongdoensis* n. sp. (Fig. 2)

*Material examined.* Holotype (Por. 88), Nammunbawi, Hongdo Island, 9 Sep. 2004, SCUBA 20 m deep, K.J. Lee and H.J. Kim, deposited in the Department of Biological Sciences, Hannam University, Daejeon, Korea.

*Description.* Irregularly thin encrusting with slightly elevated oscular rims. Sized up to 6.5 × 6 cm wide and 0.3 cm thick. Oscules 0.2-0.3 cm in diameter, located on elevated oscula rims. Color light purple in life which gradually changes to ivory in alcohol. Texture soft. Surface smooth. Ectosomal skeleton tangential arrangement and intercrossing of spicule. Choanosomal skeleton confused in arrangement of oxea and vague tracts ascend to surface in places. Spicules two kinds of oxea, no microscleres.

*Spicules.*

- Thick oxea .......................... 230-300 × 5-10 μm
- Thin oxea .................................. 180-260 × 1-3 μm

*Etymology.* This species is named after the type locality, Hongdo Island, Korea.

*Remark.* *Halichondria hongdoensis* n. sp. is similar to *H. surrugicunda* Hoshino, 1981 in type of spicule, growth form but this species has two categories (thick and thin) of oxea (Table 2).
