Production of Flavonoid Compounds and Anti-inflammatory Property of Fermented Licorice Extract with the Basidiomycete Grifola frondosa HB0071

Jun Tae Bae†, Min Hyeon Song, Jin Hwa Kim, Geun Soo Lee, and Hyeong Bae Pyo

Abstract: Liquiritigenin and isoliquiritigenin are the major flavonoids present in licorice. These flavonoid compounds were prepared by submerged culture of Grifola frondosa (G. frondosa) HB0071 mycelia producing β-glucosidase in the aqueous extract of licorice. The contents of liquiritigenin and isoliquiritigenin were increased during the fermentation. This fungus produced a high β-glucosidase (activity of 91.5 mU/mL), thereby achieving high amounts of liquiritigenin and isoliquiritigenin (568.5 µg/mL and 89.6 µg/mL), respectively at 96 h. A reversed-phase high-performance liquid chromatography method was established for simultaneous determination of liquiritigenin and isoliquiritigenin in fermented licorice extract (FLEx). The anti-inflammatory activities were investigated by licorice extract (LEX) before and after fermentation with G. frondosa HB0071. The treatment of UVB-irradiated HaCaT keratinocytes with FLEx resulted in a dose-dependent decrease in the expression level of cyclooxygenase-2 (COX-2) mRNA. Furthermore, FLEx dose-dependently decreased mRNA of the pro-inflammatory cytokines of IL-1β and IL-6 in UVB-irradiated HaCaT cells. These results suggest that FLEx may mitigate the effects of skin inflammation by reducing UVB-induced adverse skin reactions.

1. Introduction

*G. frondosa* is a Basidiomycete fungus belonging to the order Aphyllophorales, and the family Polyporaceae. *G. frondosa* has been frequently used to treat spleen and stomach ailments, to calm the nerves and the mind, and to treat hemorrhoids. Its dried fruit body has been used in the production of health foods, including teas, whole powders, powders of hot water extracts, granules, and drinks[1]. Previous work demonstrated that various biological and physicochemical properties of the extracellular polysaccharides of *G. frondosa*, which are optimization of submerged culture conditions[2], antioxidant activity, stimulation of collagen biosynthesis, cell proliferation activity, and inhibitory effect on matrix metalloproteinase (MMP-1) expression upon UVA-irradiation in cultured human dermal fibroblasts (HDFs)[3].

Licorice is a flavorful herb that has been used in food and medicinal remedies for thousands of years. It can be used for various purposes, such as bronchitis, ague, hepatitis, phthisis, and gastric ulcer[4]. Phytochemical investigation has demonstrated that the major bioactive components of licorice are flavonoids, isoflavones and triterpene saponins[5]. Among them, the remarkable flavonoids such as liquiritin, liquiritigenin (LTG), isoliquiritin, and isoliquiritigenin (ILG), are reported to have various biological activities, including antioxidative, anti-inflammatory, antimicrobial, anti-tumor, and others[6].

Phytochemicals are important secondary metabolites and are ubiquitous in all plants. They are usually synthesized in plants as a defense against pathogenic attack or environmental stress such as UV exposure or hyperhydracity[7]. Most phenolics that are found in plants, however exist conjugated to sugar (primarily glucose) as glycosides. Several studies have revealed that aglycones are superior to glycosides in various bioactivities, due to their effective absorption[8]. There is interest in increasing the amounts of aglycone components in licorice. Therefore, if free aglycones (liquiritigenin and isoliquiritigenin) in licorice root are released from their glycosides (liquiritin and isoliqui-
2. Materials and Methods

2.1. Microorganism, Media and Extraction

G. frondosa HB0071 was isolated from the mountainous district in Chungbuk province, Korea. The stock culture was maintained on potato dextrose agar (PDA) slants. Unless otherwise mentioned, slants were incubated at 27 °C for 5 days and then stored at 4 °C. The seed culture was grown in a 250 mL flask containing 50 mL of medium containing 30 g/L glucose, 6 g/L yeast extract, 2 g/L polypeptone, 0.5 g/L MgSO₄ • 7H₂O, 0.5 g/L K₂HPO₄, and 0.2 g/L MnSO₄ • 5H₂O at 27 °C on a rotary shaker incubator at 120 rpm for 5 days. Licorice was purchased from herb markets in Chungbuk province, Korea. Dried licorice (100 g) was treated with 1 L of distilled water under reflux (4 h, twice). Licorice extract was filtered and evaporated in vacuo to yield a raw residue (yield: 6.05 %).

2.2. Fermentations

Fermentation conditions were prepared as previously described[15]. Aqueous licorice extract, as the carbon source instead of glucose, was used to produce β-glucosidase and flavonoid aglycones. Fermentation were conducted at 27 °C, aeration rate 1.0 vvm, agitation speed 150 rpm, pH 5.5, and working volume 3-L for 5 days. All fermentation experiments were performed in triplicate at least.

2.3. β-glucosidase Assay

β-glucosidase from the fermented G. frondosa mycelia with licorice extract was extracted at every 24 h intervals and mycelium was removed by centrifugation (10,000 rpm, 20 min, 4 °C). The supernatant was concentrated (12,000 rpm, 20 min, 4 °C) using centrifugal filter (Vivaspin 500, 10,000 MWCO, Vivaproducts, USA). The concentrated supernatant was resuspended in 100 mM acetate buffer (pH 5.0) to give the 5-fold concentrated crude enzymes of the initial supernatant. β-glucosidase activity was routinely assayed by using a 1 mL reaction mixture containing 5 mM p-nitrophenyl-β-D-glucoside (pNP βG) (Sigma Chemical, St, Louis, MO, USA), 100 mM acetate buffer (pH 5.0), and an appropriate dilution of enzyme preparation. After 30 min of incubation at 50 °C, the reaction was stopped by adding 2 mL of 1 M Na₂CO₃, and the p-nitrophenol release was monitored at 400 nm. One unit of activity was the amount of enzyme that released 1 μmol of p-nitrophenol per min under the assay condition[16].

2.4. Analysis of Flavonoid Compounds by HPLC

The contents and compositions of flavonoid, including liquiritigenin and isoliquiritigenin from fermented and non-fermented licorice extract were determined quantitatively by HPLC. HPLC analysis was carried out by the modified method of Sakakibara et al.[17], using a Alliance Waters 2695 (Waters Co., Milford, MA, USA) system consisting of quaternary pump, auto sampler, column oven and diode array detector (Waters 996). The compounds were eluted using a Xterra RP18 column (250 × 4.6 mm i.d., Waters Co., Milford, MA, USA), joined with a guard column (10 × 4.0 mm i.d.) and detected at 275 nm and 370 nm with a flow rate of 0.8 mL/min, the column temperature was set at 35 °C. In order to isolate the region of liquiritigenin and isoliquiritigenin by flavonoid compounds with much more retention time, the elution was carried out with gradient mobile phase (A) aqueous acetic acid (6 mM) and (B) methanol, starting from 80 % A to 40 % A for 0 ~ 110 min, 40 ~ 0 % A for 10 min and 80 % A for 10 min. All extracts were completely diluted with the same amount of methanol and filtered through 0.45 μm PTFE syringe filters for injection to HPLC. Fractionation and purification of liquiritigenin and isoliquiritigenin (Figure 1) isolated from the analytical Xterra RP18 column were performed by the preparative HPLC using a Xterra RP18 preparative column (10 μm particle size, 250 × 10 mm). For the mobile phase, solvent A was methanol while solvent B was H₂O, the elution conditions were 0 ~ 10 min of 40 ~ 70 % A to B: 10 ~ 20 min of 70 ~ 75 % A to B: 20 ~ 30 min of 70 ~ 100 % A to B. The flow rate was 2.5 min/mL and injection volume was 100 μL. The flavonoid compounds peaks
Figure 1. Molecular structures of liquiritigenin and isoliquiritigenin isolated from fermented licorice extract with *G. ~frondosa* HB0071.

were collected manually. The fractions, which represented two flavonoids collected from the eluent of preparative HPLC, were lyophilized and the corresponding purified liquiritigenin and isoliquiritigenin powders were obtained. Electrospray ionization mass spectrometry (ESI-MS) (negative-ion mode) data were collected using a ion-trap time-of-flight mass spectrometer (Shimadzu LCMS-IT-TOF, Kyoto, Japan) and NMR data such as $^1$H, $^{13}$C, HSQC (heteronuclear single quantum coherence), and HMBC (heteronuclear multiple bond correlation) spectra of liquiritigenin and isoliquiritigenin dissolved in CD3OD were recorded using a 500 MHz spectrometer, (Bruker, Ettlingen, Germany).

2.5. Cell Culture

Human keratinocyte cell line, HaCaT cell, was maintained at 37 °C in a humidified atmosphere containing 5 % CO2 in Eagle’s minimum essential medium supplemented with 10 % heat inactivated FBS, 2 mM glutamine, penicillin (100 IU/mL), and streptomycin (100 µg/mL). For experiments, cell (5 × 10^4 cells/mL) were seeded in culture dish, and maintained in a tissue culture incubator.

2.6. Assay of Cell Viability

The effects of licorice extract (LEx) and fermented licorice extract (FLEx) on cell viability were evaluated using the Cell Counting Kit-8 (CCK-8) produced by Dojindo Laboratories (Tokyo, Japan). HaCaT cells were plated at a density of 3 × 10^4 cells per well in a 96-well plate, and incubated at 37 °C for 24 h. The cells were treated with various concentrations of LEx or FLEx, and incubated at 37 °C for an additional 24 h. After incubation, 10 µL of CCK-8 solution was added to each well and incubated under the same conditions for another 2 h. The resulting color was assayed at 450 nm using a microplate reader (Model ELX 800, BIOTEK Inc., Winooski, VT, USA).

2.7. UVB Irradiation, RNA Isolation and RT-PCR

HaCaT cells were seeded into 96-well plates and cultured overnight, UVB irradiation doses were 40 mJ/cm^2 and the radiation intensity was measured using UV radiometer (EKO, JAPAN). RNA was extracted using a Intron easy-BLUETM Total RNA Extraction Kit (iNtRON Biotechnology, Korea) according to the supplier’s instructions. A reverse-transcriptase polymerase chain reaction (RT-PCR) was performed to synthesize cDNA. PCR was then performed with each cDNA of COX-2, IL-6, IL-1β and GAPDH (the internal standard) fragments, primers, and Tag DNA polymerase. The primers used were as follows: 5′-TCC ACA GCC AGA CGC CCT CA-3′ (forward) and 5′-GGC CCA GCC CGT TGG TGA AA-3′ (reverse) for COX-2; 5′-AGC GCC TTC GGT CCA GTT GC-3′ (forward) and 5′-GCT TCG TCA GCA GGC TGG GGA TTG GCC CT-3′ (reverse) for IL-6; 5′-ATC GCA CGC TCC GGG ACT CA-3′ (forward) and 5′-AAG GGC TGG TGA TGG GCC CT-3′ (reverse) for IL-1β 5′-ATT GTT GCC AAT ATC AAT TAG CCG CC-3′ (forward) and 5′-AGT AGA GCC AGG GAT GAT.
GT-3′ (reverse) for GAPDH. Reactions were carried out in an automatic heat-block DNA thermal cycler (ASTEC PC801, ASTEC Inc, Tokyo, Japan) for 22 cycles: denaturation for 60 s at 94 °C annealing for 60 s at 60 °C extension for 60 s at 72 °C. PCR products were electrophoresed on a 1.5 % agarose gel in TAE (40 mM Tris acetate, 1 mM EDTA) and visualized by ethidium bromide staining. Gel images were scanned using a CS analyzer 2.0 (ATTO, Tokyo, Japan).

2.8. Statistical Analysis
All experiments were performed in triplicate. Data were presented as meanstandard error (SE). Statistical comparison was conducted using Student’s t-test after ANOVA. The results are considered to be significant when p < 0.05.

3. Results and Discussion

3.1. Fermentation for Flavonoid Aglycones Production
Licorice (Glycyrrhizae radix) is one of the oldest and most frequently used botanicals in oriental medicine. A large number of components have been isolated from licorice, including triterpene saponins, flavonoids, isoflavonoids and chalcones[6]. We investigated the transformation of flavonoid glycosides of licorice extract to liquiritigenin (aglycone of liquiritin) and isoliquiritigenin (aglycone of isoliquiritin) production using β-glucosidase produced from a submerged culture of G. frondosa HB0071. In plants, flavonoids are usually found in conjugated forms through hydroxyl groups with sugar as glycosides.

To obtain bioactive flavonoids by enzymatic hydrolysis from different beverages and cereals, many investigators have studied submerged fermentation of microorganism and some basidiomycete mushrooms for β-glucosidase production[18]. Figure 2 shows the typical time profiles of mycelial growth and β-glucosidase activity in the fermented licorice extract with G. frondosa HB0071. The maximum mycelial biomass and β-glucosidase activity were 25.3 g/L and 91.5 mU/mL, respectively. To examine whether liquiritigenin and isoliquiritigenin in licorice extract were increase by the fermentation by G. frondosa, the detected major peaks in licorice extract and fermented licorice extract were analyzed by HPLC. Figure 3 shows the HPLC chromatogram at 327 nm of licorice extract (Figure 3A) fermented with G. frondosa HB0071 mycelium (Figure 3B) for 96 h. As shown in Figure 3B, the new peaks of compound 1 (C1) and compound 2 (C2) were detected and identified by their retention times and UV spectra and by comparison with liquiritigenin and isoliquiritigenin as standards (Figure 3C). The isolated C1 and C2 were identified by MS, 1H NMR, and 13C NMR analyses and were characterized as liquiritigenin and isoliquiritigenin, respectively. Their characteristics were analyzed and showed the follows: (1) liquiritigenin: colorless amorphous powder; negative ESI-MS (C15H12O4) m/z: 257 [M-H]: 1H-NMR (500 MHz, METHANOL-D4): δ 5.38 (1H, dd, J=3.0, 13.0 Hz, H-2), 3.05 (1H, dd, J=13.0, 16.5 Hz, Ha-3), 2.47 (1H, dd, J=3.0, 16.5 Hz, Hb-3), 7.73 (1H, d, J=8.5 Hz, H-5), 6.49 (1H, dd, J=2.5, 8.5 Hz, H-6), 6.35 (1H, d, J=2.5 Hz, H-8), 7.32 (2H, d, J=8.5 Hz, H-2’, 6’), 6.81 (2H, d, J=8.5 Hz, H-3’, 5’); 13C-NMR (125 MHz, METHANOL-D4): δ 81.2 (C-2), 45.1 (C-3), 193.6 (C-4), 130.0 (C-5), 111.9 (C-6), 167.1 (C-7), 103.9 (C-8), 165.7 (C-9), 115.0 (C-10), 131.5 (C-1’), 129.1 (C-2’, 116.4 (C-3’, 159.1 (C-4’, 116.4

consistent with the literature with respect to liquiritigenin and isoliquiritigenin[19]. The molecular structures of the above two flavonoids from purified fermented licorice extract are shown in Figure 1.

To begin to study the anti-inflammatory activities of aqueous licorice extracts before and after fermentation with G. frondosa HB0071, the changed contents and yield of aglycones on the bioconversion were investigated. As shown in Table 1, the contents of liquiritigenin and isoliquiritigenin increased from 1.92 and 0.72 µg/mL at the start of the process to 568.54 and 89.62 µg/mL after 96 h of fermentation, respectively. Figure 4 shows that the contents of liquiritigenin (compound 1) and isoliquiritigenin (compound 2) increased significantly during fermentation by G. frondosa. This could be attributed to being hydrolyzed.

and used as a carbon source for mycelial growth and metabolite production. Many studies have been carried out on β-glucosidase, which catalyzes the hydrolysis of the glycosidic bond between two or more carbohydrates or between a carbohydrate and a non-carbohydrate moiety[20]. Miura et al.[21] reported that the basidiomycete, Ganoderma lucidum could convert isoflavone glycosides to aglycones by its β-glucosidase activity. In plants, natural phenolics are usually found as glycosides, and the sugar species and binding forms show great variety[22]. Several investigators reported that licorice contains most glycoside compounds, such as glycyrrhizin, liquiritin, and isoliquiritin, but aglycones are relatively low from results of HPLC analysis [23]. Recently, Li et al.[24] reported that the liquiritin, isoliquiritin, liquiritigenin, and isoliquiritigenin contents of 17 licorice samples from different locations in China were 7.3 ∼ 23.2, 2.1 ∼ 7.7, 0.1 ∼ 1.9 and 0.1 ∼ 0.7 mg/g, respectively.

In this study, there were a greater amount of liquiritin and isoliquiritin than liquiritigenin and isoliquiritigenin in aqueous licorice extracts due to the poor water-solubility characteristics of flavonoid aglycones (data not shown). Interestingly, however, liquiritigenin and isoliquiritigenin contents increased after fermentation (Table 1). This may be due to the fact that the hydrolytic enzyme β-glucosidase produced by G. frondosa HB0071 catalyzes the release of flavonoid aglycones from licorice extract substrate, thereby resulting in an increase in aglycone content.

3.2. Effect of Fermented Licorice Extract on UVB-Irradiated HaCaT Keratinocytes

Reactive oxygen species (ROS) such as hydroxyl and superoxide radicals produced by sunlight, ultraviolet, chemical reactions, and metabolic processes have a wide variety of pathological effects on cellular processes[25]. Exposure of skin to UVB radiation results in a variety of biological effects, including inflammation, sunburn cell formation, immunologic alterations, and photo-aging[26]. Keratinocytes respond to the major changes in the inflammation and immune-modulation observed after UVB exposure, at least via the UVB-induced release of inflammatory mediators, such as cytokines and prostaglandins[10]. COX-2 is a pivotal player in inflammatory processes, and UV radiation is a known stimulus for COX-2 expression in skin cells. Fernau et al.[27] reported that COX-2 expression in HaCaT human keratinocytes was observed only upon exposure of cells to UVB (280 ∼ 320 nm) but not to UVA radiation (320 ∼ 400 nm). In the present study we found that treatment of fermented licorice extract (FLEX) with HaCaT keratinocytes suppressed UVB-induced reduction of cell viability and production of inflammatory mediators.
HaCaT cells were treated with various concentrations of licorice extract and FLEX for 24 h, and the cell viability was tested by a CCK-8 assay. As shown in Figure 5, neither LEX nor FLEX (under 100 µg/mL) had a significantly cytotoxic effect on the HaCaT cells, whereas FLEX had less cytotoxicity compared with LEX at higher concentrations (above 200 µg/mL).

To investigate whether LEX and FLEX inhibit UVB-induced COX-2 expression, HaCaT cells were exposed to UVB (40 mJ/cm²). Thus, in the present study the effects of LEX and FLEX upon UVB irradiation were examined by measuring the steady-state COX-2 mRNA level in relation to GAPDH mRNA levels. As shown in Figure 6, the expression of COX-2 mRNA in UVB-irradiated HaCaT cells was significantly reduced by FLEX in a dose-dependent manner, while LEX-treated COX-2 mRNA had a relatively lower level compared with that of FLEX. These results are associated with the higher concentration of liquiritigenin and isoliquiritigenin produced from licorice extract with G. frondosa HB0071 than that of licorice extract, which has a higher ratio of flavonoid glycosides. In addition, mRNA expression of IL-1β and IL-6 in UVB-irradiated HaCaT keratinocytes was determined by RT-PCR analysis. Treatment of UVB-irradiated HaCaT cells with FLEX concentrations of 25, 50, and 100 µg/mL dose dependently reduced the elevated IL-1β and IL-6 mRNA expression significantly, as shown in Figure 7. Remarkably, the expression of IL-6 mRNA in UVB-irradiated HaCaT cells was almost completely inhibited (by about 90%) at a FLEX concentration of 100 µg/mL.

Kim et al.[11] reported that isoliquiritigenin isolated from the roots of Glycyrrhiza uralensis reduced the LPS-induced expressions of inducible nitric oxide synthase (iNOS), COX-2, and pro-inflammatory cytokines (TNF-α, IL-1β, and IL-6) at the protein and mRNA levels in a dose-dependent manner in macrophages. They also suggested that flavonoid glycosides are possibly due to their different affinities for cellular membranes because affinity for cellular membranes appears to play an important role in the cellular uptake of lipophilic compounds by passive diffusion and because isoliquiritin possesses a sugar moiety, which would reduce its lipophilicity and compatibility with cellular membranes.

Other investigators have reported that liquiritigenin significantly inhibited LPS-induced TNF-α, IL-1β, and IL-6 secretions. They found that the suppressive effects of liquiritigenin on IL-1β or IL-6 production were greater than its effect on TNF-α, which supports the possibility that liquiritigenin has a greater in
Figure 7. Inhibitory effect of FLEx on UVB-induced mRNA expression of IL-6 and IL-1β. HaCaT cells were cultured in the presence of various concentrations of LEx and FLEx (25 ~ 100 µg/mL) for 24 h, respectively. * p < 0.05 compared with UVB (UVB: 40 mJ/cm²). hibitory effect on the production of secondary cytokines[28].

4. Conclusion

In summary, our results demonstrated that fermented licorice extract with G. frondosa HB0071 was very effective for the improvement of flavonoid aglycones (liquiritigenin and isoliquiritigenin) contents and inhibitory effects on UVB-induced inflammation in HaCaT keratinocytes. We also investigated that exo-polysaccharide (EPS) was produced from submerged culture of aqueous licorice extract with G. frondosa mycelia (data not shown). As we previously found, EPS has an inhibitory effect on MMP-1 expression in UVA-irradiated human dermal fibroblasts (HDFs) [3]. Therefore, EPS and other metabolites that produced FLEx could possibly affect the inhibitory action in photo-aging skin by reducing the MMP 1-related matrix degradation system. Our results suggest that FLEx, a mixture containing flavonoid aglycones and exo-polysaccharides produced by G. frondosa HB0071 mycelia, is a potential candidate to reduce UV-induced skin inflammation. In the future, combinations of other natural compounds may be considered for more efficient photoprotection, and further studies for elucidating overall biological functions of FLEx in vivo should be performed.
