Despite the fact that many cancer cells are sensitive to TNF-related apoptosis-inducing ligand (TRAIL)-induced apoptosis, some cancer cells show either partial or complete resistance to TRAIL. Human leukemic K562 and CEM cells also show resistance to TRAIL-induced apoptosis. Novel molecular target and treatment strategies are required to overcome TRAIL resistance of human leukemia cells. Therefore, the purpose of this study was to target key anti-apoptotic molecules deciding TRAIL resistance for sensitization of TRAIL-resistant K562 and CEM cells, and to evaluate the effect of quercetin as a TRAIL sensitizer on these TRAIL-resistant cells. We found that quercetin acted in synergy with TRAIL to enhance TRAIL-induced apoptosis in K562 cells by inhibition of the DNA-PK/Akt signaling pathway, which leads to enhancement of TRAIL-mediated activation of caspases and concurrent cleavage of PARP and up-regulation of Bax. The findings suggest that the DNA-PK/Akt signaling pathway plays an essential role in regulating cells to escape from TRAIL-induced apoptosis, and quercetin could act in synergy with TRAIL to increase apoptosis by inhibition of the DNA-PK/Akt signaling pathway, which overcomes TRAIL-resistance of K562 and CEM cells. This study suggests that DNA-PK might interfere with TRAIL-induced apoptosis in human leukemic cells through activation of the Akt signaling pathway.

Key words: Quercetin, DNA-PK/Akt signaling pathway, TRAIL, K562 cells, CEM cells

Introduction

TNF-related apoptosis-inducing ligand (TRAIL) is a promising cancer therapy that preferentially induces apoptosis in cancer cells [3,21,27,40]. TRAIL is a transmembrane protein that functions by binding to two closely related receptors, DR4 and DR5. TRAIL is capable of inducing apoptosis in a wide variety of cancer cells but some cancer cell lines show either partial or complete resistance to the pro-apoptotic effects of TRAIL [9,22,28,32,34]. The reason for the TRAIL resistance is not regulated solely by the differential expression of the receptors. Instead, it appears to be more likely that intracellular inhibitors acting downstream of TRAIL receptors render some cells insensitive to TRAIL since the resistance of many types of cancer cells to TRAIL can be reversed by treatment with chemotherapeutic agents or protein synthesis inhibitors [3,4,10,13,14,17,29,38]. It has been reported that human leukemic cells showed resistant to TRAIL-induced apoptosis [6,25,31]. The study of the intracellular mechanisms that control TRAIL resistance of these leukemic cells might enhance our knowledge of death receptor-mediated signaling and help to develop TRAIL-based approaches for treatment of human leukemia.

There are many factors contributing to the resistance to TRAIL-induced apoptosis. Among the cellular signaling pathways that promote cell survival, Akt, a serine/threonine protein kinase, is one of the important survival factors that contribute resistance to TRAIL [7,23,24,30]. Previous studies have shown that Akt is implicated in mediating a variety of biological responses and plays an important role in survival when cells are exposed to various kinds of apoptotic stimuli [2,26,36]. In fact, Akt has been demonstrated to inhibit apoptosis and cytochrome c release induced by several pro-apoptotic Bcl-2 family members [18]. A recent report suggests that phosphorylation of Akt at Ser473 may be mediated by DNA-dependent protein kinase (DNA-PK) [11]. DNA-PK, a member of the PI3K-related kinase subfamily of protein kinases, is a three-protein complex consisting of
a 470-kDa catalytic subunit (DNA-PKcs) and the regulatory DNA binding subunits, Ku heterodimer (Ku70 and Ku80) and DNA-PK plays an important role in DNA repair and protects cells from apoptosis induced by DNA damaging agents [39]. DNA-PKcs colocalized with Akt and enhanced Akt phosphorylation. Although Akt plays a critical role in cell survival, the involvement of DNA-PK in the anti-apoptotic function of Akt has not been investigated.

Resistance to TRAIL is an important therapeutic problem that may be circumvented by combination treatments that act by various mechanisms including a decrease in c-FLIP levels or restoration of caspase 8 expression [15,33]. As most agents used in such combinations are inherently toxic, it is imperative to find nontoxic agents. It has been shown that quercetin, a ubiquitous bioactive plant flavonoid, promotes TRAIL-induced apoptotic death by dephosphorylation of Akt in Human prostate adenocarcinoma cells [20]. Quercetin has a wide range of biological activities including induction of apoptosis and inhibition of various enzymes involved in proliferation and in the signal transduction pathway [12].

Here, we suggest a new resistance mechanism of TRAIL that the DNA-PK pathway plays an essential role in regulating cells to escape from TRAIL-induced apoptosis. We found that quercetin could act in synergy with TRAIL to increase apoptosis by down-regulation of DNA-PK and thus overcome TRAIL-resistance of human leukemic K562 or CEM cells. This study is the first to show that the DNA-PK pathway could interfere with TRAIL-induced apoptotic signaling in human leukemic cells through activation of Akt signaling pathway.

**Materials and Methods**

**Cell culture**

Human chronic myelogenous leukemia (CML) K562 cells and human leukemic lymphoid CCRF-CEM (CEM) cells were maintained in culture in RPMI medium containing 10% fetal bovine serum and antibiotics.

**Proliferation assays**

Cell proliferation was measured either by counting viable cells by using the 3-(4, 5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT; Sigma Chemical Company, St. Louis, MO) colorimetric dye-reduction method. Following the removal of conditioned medium after 5 days of TRAIL and/or quercetin exposure, cells in 96-well plates were incubated with 5 mg/ml MTT for 4 h. After centrifugation, the medium was aspirated and MTT-formazan crystals solubilized in 100 μl DMSO. The optical density of each sample at 570 nm was measured using ELISA reader. The optical density of the media was proportional to the number of viable cells. The level of inhibition was measured as a percentage of control growth (no drug in the sample). All experiments were repeated at least two experiments in triplicate.

**Western blot analysis**

Protein samples were separated by SDS-PAGE and blotted to nitrocellulose membrane (Hybond-ECL, GE Healthcare). The membrane was incubated with antibody as specified, followed by secondary antibody conjugated with horse-radish peroxidase. Specific antigen-antibody complexes were detected by enhanced chemiluminescence (PerkinElmer, Life science). Western blot analysis was performed with the following antibodies: anti-Ku70/Ku80, p-Bad, Caspase 3, PARP, Bcl-2, p53 and Bax antibodies (Santa Cruz Biotechnology, CA), anti-Akt, phospho-Akt (Ser 473), Caspase 8 and Caspase 9 antibodies (Cell Signaling Technology, MA), anti-Hsp70 and β-actin antibodies (Sigma-Aldrich), anti-DNA-PKcs antibody (Thermo Fisher Scientific, CA), anti-DR5 (Cellbiochem, Germany) and anti-DR4 antibody (R&D Systems, MN). Secondary antibodies were obtained from GE Healthcare.

**Cell extract preparation and electrophoretic mobility shift assay (EMSA)**

Nuclear extracts were prepared from TRAIL and/or quercetin cells as described previously [37]. In brief, 3×10^6 cells were washed with cold phosphate buffered saline and harvested quickly and resuspended in 300 μl of lysis buffer [10 mM HEPES, pH 7.9, 1.5 mM MgCl2, 10 mM KCl, 0.5 mM dithiothreitol (DTT), 0.5 mM phenyl methyl sulphonyl fluoride (PMSF)]. The cells were allowed swelling in ice for 10 min. After 0.05% Nonidet P40 was added, the tube was vigorously mixed 3 times for 3 sec on a vortex, and centrifuged at 250×g for 10 min to pellet the nuclei. The nuclear pellet was resuspended in 30 μl of ice-cold nuclear extraction buffer (5 mM HEPES, pH 7.9, and 26% glycerol (v/v), 1.5 mM MgCl₂, 0.2 mM EDTA, 0.5 mM DTT, 0.5 mM PMSF), and then incubated on ice for 30 min with intermittent mixing, and centrifuged at 24,000×g for 20 min at 4°C. The nuclear extract was either used immediately or stored at -70°C for
later use. 10 μg of nuclear extract was incubated with 32P-labeled double-stranded oligonucleotide, 5'-AGTGGAGGGG CTCTCCCAGGC-3' for Ku binding in binding buffer [10 mM Tris-HCl, pH 7.9, 50 mM NaCl, 1 mM MgCl2, 0.5 mM EDTA, 4% glycerol containing 50 μg/ml of poly (dI-dC)]. The DNA-protein complex was separated from free oligonucleotide on 4% nondenaturing polyacrylamide gel using 0.5× TBE buffer (44.4 mM Tris-HCl, pH 8.0, 44.5 mM boric acid, 1 mM EDTA) for 3 hr at 120 V. The gels were dried and autoradiographed.

DNA-dependent protein kinase assay

The kinase activity of DNA-PK was determined using the Signa TBCTM DNA-dependent Protein Kinase Assay System (Promega Corp., Madison, WI). In brief, 10 μg of nuclear extract was incubated with activator DNA, a biotinylated p53-derived peptide substrate, and [γ-32P] ATP at 30°C for 5 min. The sample was terminated by adding termination buffer. Each termination reaction sample was spotted onto SAM2TM Biotin Capture Membrane and washed with 2 M NaCl and 2 M NaCl in 1% H3PO4. The SAM2TM Membrane squares were analyzed using Molecular Imager System (Bio-Rad Laboratories, Inc., Model GS 525, Hercules, CA).

Apoptosis assessment by Annexin V staining

K562 and CEM cells (2×105 cells/ml) were treated with or without TRAIL and/or quercetin for 24 hr. After this, the cells were centrifuged and resuspended in 500 μl of the staining solution containing Annexin V fluorescein (FITC Apoptosis detection kit; BD ParMingen San Diego, CA) and propidium iodide in PBS. After incubation at room temperature for 15 min, cells were analyzed by flow cytometry. Annexin V binds to those cells that express phosphatidyl serine on the outer layer of the cell membrane, and propidium iodide stains the cellular DNA of those cells that have a compromised cell membrane. This allows for the discrimination of live cells (unstained with either fluorochrome) from apoptotic cells (stained only with Annexin V) and necrotic cells (stained with both Annexin V and propidium iodide).

Results

Quercetin induced sensitization of TRAIL-resistant K562 cells to TRAIL

Primary or cultured leukemia cells are resistant to TRAIL (TNF-related apoptosis-inducing ligand)-induced apoptosis [16]. The molecular factors regulating the sensitivity to TRAIL are still incompletely understood in the TRAIL-resistant cells. Therefore, to investigate the potential mechanism of leukemic cells resistant to TRAIL, we determined the susceptibility to TRAIL-induced apoptosis of K562 cells. When K562 cells were treated with TRAIL (10- and 50 ng/ml) for 24 hr, TRAIL-induced apoptosis in K562 cells was not observed with TRAIL alone (Fig. 1A).

In search of novel strategy to target TRAIL-resistant K562 cells, the effect of chemopreventive, natural compound quercetin on sensitivity of TRAIL in K562 cells was determined since it is known that quercetin possesses the activity of Akt dephosphorylation, one of critical modulator of TRAIL sensitivity. We therefore examined whether quercetin could promote and sensitize to TRAIL-induced apoptosis in TRAIL-resistant K562 cells by combined treatment of quercetin and TRAIL (Fig. 1B). When K562 cells were treated with TRAIL (10- and 50 ng/ml) in the presence or absence of quercetin (20 μM) for 24 hr, TRAIL-induced apoptosis in K562 cells was not observed with TRAIL alone but combined

![Fig. 1. Synergistic effect of quercetin on TRAIL-induced apoptosis in K562 cells. Cells were treated with TRAIL (10 or 50 ng/ml) (A) in the presence or absence quercetin (20 μM) of for 48 hr (B). Thereafter, the percentage of apoptotic cells in each cell population was determined by Annexin V staining and flow cytometry. Each point is the average of triplicate determinants (P<0.05).](image-url)
treatment of TRAIL and quercetin resulted in an increase of apoptosis in K562 cells. This result indicated that quercetin and TRAIL acted synergistically to induce apoptosis.

Down-regulation of DNA-PK is associated with an increase in susceptibility to TRAIL-induced apoptosis

It has been reported that constitutively active Akt is an important regulator of TRAIL sensitivity and elevated Akt activity inhibited TRAIL-induced apoptosis [5]. Since DNA-PKcs phosphorylates Akt at Ser473 [29] and the high level of phosphorylated Akt (p-Akt) is closely correlated with TRAIL resistance, we investigated whether DNA-PK could be involved in modulation of TRAIL sensitivity. To determine the effect of quercetin on DNA-PK signaling pathway against K562 cells, the cells were treated with various doses of quercetin (20 ~ 200 μM), and the changed levels of DNA-PKcs, p-Akt and total Akt (t-Akt) were determined (Fig. 2). The levels of DNA-PKcs and p-Akt were significantly reduced by quercetin at high concentrations (100- and 200 μM) but the level of t-Akt was not changed under same condition. We further determined whether cleavage of PARP and modulation of Ku, the other components of the DNA-PK, by quercetin treatment. K562 cells treated with quercetin showed cleavage of PARP and reduction of Ku70/Ku80 and its DNA-binding activity, dose-dependently.

These results suggest that down-regulation of DNA-PK might be associated with an increase in susceptibility to TRAIL-induced apoptosis via reduction of Akt phosphorylation. We next determined whether inhibition of DNA-PK/Akt pathway and subsequently activation of apoptosis machinery occurred in K562 cells by combined treatment of quercetin (20 μM) and TRAIL (10- or 50 ng/ml) (Fig. 3A). As
expected, the levels of both DNA-PKcs and p-Akt synergistically reduced but total Akt did not affect level by co-treatment of K562 with TRAIL and quercetin. Also, synergistic reduction of DNA-PK kinase activity and subsequently activation of apoptosis machinery was observed in K562 cells treated with quercetin and TRAIL. The cleavage of PARP and concurrent down-regulation of Bcl-2 and up-regulation of Bax were occurred in K562 cells co-treated with TRAIL and quercetin, whereas the cells treated with TRAIL alone showed neither cleavage of PARP nor changed level of Bcl-2 and Bax. Because the anti-apoptotic protein Bad, a downstream target of Akt, which is phosphorylated by Akt, we also investigated the level of phosphorylation of Bad (pBad). In K562 cells co-treated with TRAIL and quercetin, the level of p-Bad as well as p-Akt was decreased. Our results revealed that inhibition DNA-PK and subsequent Akt signaling pathway is required for TRAIL-induced apoptosis and therefore quercetin might be enhanced TRAIL sensitivity in K562 cells through inhibition of DNA-PK/Akt signaling pathway.

Effect of quercetin on TRAIL-induced apoptosis of K562 cells by caspase activation

Since it has been known that TRAIL-induced apoptosis can be increase by increasing TRAIL receptor expression and down-regulation of c-FLIP, we also determined whether quercetin promotes TRAIL-induced apoptotic death by modulating the level of DR4/DR5 or c-FLIP. Data from Western blot analysis revealed that the combined treatment of TRAIL (10- or 50 ng/ml) and quercetin (20 μM) did not significantly alter the level of DR4/DR5 or c-FLIP, protein expression. From these results, inactivation of DNA-PK/Akt signaling pathway but not receptor-dependent death signals by quercetin could be required for sensitization of K562 cells to TRAIL (Fig. 3B).

On the other hand, TRAIL-induced apoptosis requires the activation of caspases and PARP cleavage is a hallmark of caspase activation. TRAIL-induced activation of caspase 8 leads to activation of downstream caspases including caspase 9 and -3. To determine whether quercetin enhances TRAIL-induced apoptosis by increasing the activation of caspases, K562 cells were treated quercetin (20 μM) in the presence or absence of TRAIL (10- or 50 ng/ml), and then changed activity of caspase was determined (Fig. 3C). Combined treatment of quercetin and TRAIL gradually and synergistically induced the proteolytic processing of procaspase 8, quercetin dose-dependently but quercetin or TRAIL alone did not induce significant level of proteolytic processing of procaspase 8. Similar results were observed for caspase 9 and caspase 3 activation by combined quercetin and TRAIL treatment. K562 cells co-treated with quercetin and TRAIL showed activation of both caspase 9 and caspase 3, whereas quercetin or TRAIL alone did not in and degradation of PARP due the activation of these caspases. Moreover, the combined treatment of quercetin and TRAIL causes severe cleavage of PARP.
When produced we associated of Fig. 1028 (B) Since PARP.

Fig. 4. The effect of TRAIL molecule on quercetin-induced modulation of DNA-PK/Akt and apoptosis-related molecules and its effect on modulation of caspases in K562 cells. Cells were treated with graded doses of quercetin (20, 100- and 200 μM) in the presence or absence of TRAIL (50 ng/ml) for 4 hr, and then harvested. Western blot analysis was performed to monitor levels of DNA-PKcs, total Akt, p-Akt, Hsp70, Bax and Bcl-2 (A). The activation of caspases 3,8 and -9 and PARP cleavage were determined by western blot analysis (B). CF: cleavage fragment.

whereas quercetin or TRAIL alone failed to induce cleavage of PARP. These results showed that TRAIL enhanced quercetin-induced activation of the caspases 8, -9, -3 and the associated cleavage of PARP.

Sensitization of CEM cells to TRAIL by quercetin

Since we found that quercetin enhanced TRAIL response of K562 cells by inhibition of DNA-PK signaling pathway, we also examined whether quercetin promotes TRAIL-induced apoptosis in other human leukemic cells (Fig. 5). When human leukemic lymphoid CEM cells were treated with TRAIL (2- and 10 ng/ml) for 24 hr, TRAIL-induced apoptosis in CEM cells was not observed with TRAIL alone. However, CEM cells, like K562 cells, clearly showed that TRAIL-mediated apoptosis was synergistically enhanced by quercetin. We observed that quercetin acted in synergy with TRAIL to increase apoptosis in CEM cells in a dose-dependent manner. To check the effect of quercetin on DNA-PK signaling pathway against CEM cells, the cells were treated with various doses of quercetin (20-200 μM) and the changed levels of DNA-PKcs, p-Akt, total Akt and were determined (Fig. 6A). CEM cells showed that the levels of DNA-PKcs and p-Akt were significantly reduced but the level of total Akt was not changed by treatment of quercetin at high concentrations (100- and 200 μM), which is almost the same results in K562 cells. We next determined whether quercetin enhances TRAIL-induced apoptosis by increasing the inhibition of DNA-PK/Akt signaling cascade and PARP cleavage (Fig. 6B). The levels of both DNA-PKcs and p-Akt in CEM cells were synergistically decreased but total Akt did not affect level by co-treatment of TRAIL and quercetin. The kinase activity of whole DNA-PK complex was also decreased in CEM cells by combined treatment of quercetin and TRAIL. PARP cleavage was remarkably accelerated in the cells co-treated with TRAIL and quercetin than TRAIL or quercetin alone.

Therefore, our results suggest that activation of DNA-PK pathway limits TRAIL-induced apoptosis via Akt activation and thus quercetin acts in synergy with TRAIL to enhance
TRAIL-induced apoptosis in human leukemia cells such as K562 and CEM cells by inhibition of DNA-PK as well as Akt signaling pathway, which leads to TRAIL-mediated activation of caspase, and PARP cleavage. This model provides a framework for overcoming of TRAIL resistance of other cancer cells by combined treatment of TRAIL and agent that targeted inhibition of DNA-PK activity.

Discussion

Induction of apoptosis in cancer cells by TRAIL is a promising therapeutic principle in oncology, although toxicity and resistance against TRAIL are limiting factors. Indeed, many tumors remain resistant towards treatment with TRAIL, which has been related to the dominance of anti-apoptotic signals. Therefore, the purpose of this study was to target key anti-apoptotic molecules deciding TRAIL resistance for sensitization of TRAIL-resistant human leukemic cells such as K562 and CEM cells. We found that DNA-PK could interfere with TRAIL-induced apoptosis in human leukemic cells through activation of Akt signaling pathway and DNA-PK/Akt signaling pathway plays an essential role in regulating cells to escape from TRAIL-induced apoptosis.

A variety of reports has suggested the role of Akt in chemotherapy resistance to apoptosis and indicated its pro-survival function [7,23,24,26,30]. Indeed, it has been reported that activated Akt subsequently phosphorylates and inactivates several proapoptotic molecules including TRAIL and thus down-regulation of Akt activity promotes TRAIL cytotoxicity [2,36].

In addition to having a role in DSB repair of DNA-PK, the DNA-PK catalytic subunit, a member of PBK family, performs an essential phosphorylation on Akt Ser-473 [8]. Since DNA-PKcs physiologically interacts with and activates Akt, it is very possible that both DNA-PK and Akt activities contribute to cancerous cell survival.

In this study, we suggest that the susceptibility to TRAIL-induced cytotoxicity is associated with inhibition of DNA-PK/Akt signaling cascade in human leukemic cells. K562 cells expressing constitutive high level of p-Akt and DNA-PKcs exhibited resistant to TRAIL, whereas K562/R3 variant isolated from K562 cells displaying loss of DNA-PKcs/p-Akt level and their kinase activities through inactivation of DNA-PK/Akt signaling cascade exhibited rather hypersensitivity to TRAIL (data not shown). Therefore, our data indicated the possibility that K562 cells protect against TRAIL-induced apoptosis by activation of DNA-PK/Akt signaling pathway, and target them to induce growth inhibition and apoptosis in response to TRAIL. It indicated that targeting of DNA-PK as a key modulator of TRAIL responsiveness could help to design TRAIL-based combinations for treatment of human leukemia cells.

DNA-PK acts upstream to Akt and is important for both phosphorylation and activation of Akt. Indeed, it has been reported that tumor cells resistant to anticancer drugs show increases in both DNA-PK expression and its kinase activity [35], and the use of inhibitor that possesses inhibitory action of DNA-PK activity improved the effectiveness of anticancer drug [19,41], suggesting that DNA-PK may play an important role in the development of drug resistance. Therefore, TRAIL in combination with agents that down-regulate DNA-PK can have clinical applicability in treating TRAIL-insensitive human leukemic cells.
Quercetin is known to inhibit Akt phosphorylation as well as
experts multiple effects on cellular growth and apoptosis
[34]. We found that quercetin possesses inhibitory action of
expression and activity of both DNA-PK and Akt at high
concentration, suggesting possibility that quercetin could
potentiate TRAIL-induced apoptosis by inhibition of
DNA-PK and p-Akt signaling cascade.

Our data showed that quercetin potentiated TRAIL-
mediated cytotoxicity and synergistically enhanced apoptosis
when K562 cells were co-treated with TRAIL and quercetin,
suggesting the possibility that TRAIL-resistance of leukemic
cells could be overcome and restored TRAIL sensitivity by
quercetin. We revealed the molecular mechanism that quercetin
acted in synergy with the TRAIL to increase apoptosis
in leukemic cells. By combination of these agents, inhibition
of Akt phosphorylation via down-regulation of DNA-PK
was occurred in the cells, which consequently led to
TRAIL-mediated activation of caspase such as caspase 3, -8
-9 and cleavage of PARP. Concurrently, up-regulation of Bax
down-regulation of Bel-2 were observed in the cells
treated with these agents but treatment with quercetin or
TRAIL alone did not significantly modulate this signaling
cascade. From these results, inhibition of DNA-PK/Akt sig-
naling pathway but not receptor-dependent death signals by
quercetin could be required for sensitization of K562 cells
to TRAIL. A similar mechanism is operative in other human
leukemic CEL cells. Quercetin sensitizes TRAIL-resistant
CEL cells expressing constitutive high level of DNA-PK and
p-Akt to TRAIL-induced apoptosis by inhibition of DNA-
PK/Akt signaling pathway.

Therefore, quercetin is a potent promoter of TRAIL-
induced apoptosis and thus might be a candidate to overcome
resistance of TRAIL-insensitive other cancer cells expressing
constitutive high level of DNA-PK. Therefore, selective
inhibition of DNA-PK/Akt signaling pathway may be benefi-
cial for anticancer therapy of TRAIL.

Overall, our study provides important insights into how
quercetin promotes TRAIL-induced apoptosis against
TRAIL-resistant human leukemic cells and this model pro-
vides a framework for overcoming of TRAIL resistance of
other cancer cells including prostate, lung, ovarian and
breast cancer cells.

TNF-related apoptosis-inducing ligand (TRAIL)는 암세포에만 작용하고 정상세포에는 영향을 주지 않는 항암제로서 알려져 있지만, TRAIL에 내성을 나타내는 암세포의 출현이 문제점으로 지적되고 있다. 사람 백혈병세포인 K562 및 CEM 세포는 TRAIL에 내성을 나타낸다. 본 연구에서는 이러한 백혈병 세포의 TRAIL 내성에 대한 새로운 표적 분자의 발굴과 이를 토대로 한 새로운 내성극복 방법을 연구하였다. 새로운 TRAIL sensitizer로서 quercetin을 발굴하고, 이를 K562 세포에 TRAIL과 병용 투여하므로 TRAIL의 효과 증가에 의한 내성극복을 시도하였다. Quercetin은 DNA-PK/Akt 신호전달경로를 억제하므로, caspases 활성 증가와 PARP cleavage, 이에 따른 Bax의 발현을 증가시키는 기전으로 K562 세포의 TRAIL에 의한 apoptosis를 증가시키는 활성을 보였다. 이러한 quercetin 병용 처리에 의한 TRAIL의 활성 증가로 TRAIL 내성을 극복할 수된 CEM 세포에서도 확인하였다. 이러한 연구 결과는 DNA-PK 활성 증가에 의한 Akt의 활성화가 TRAIL 내성을 유발하는 기전을 토대로 함을 밝히므로써, DNA-PK 활성 억제제를 TRAIL과 병용하므로 TRAIL 내성을 나타내는 암세포에 내성 극복 효과를 얻을 수 있는 새로운 약제 병용 방법을 제시하였다.
